

# AVD Extended Workshop

Intro into Ansible, Ansible AVD, Git and  
VSCode for new and existing AVD users

## What is this Workshop about?

- This workshop is split into 3 sections. Each section takes around 2 hours to complete. That can be done as a full day workshop or split into 3 separate sessions.
- Topics:
  - Section 1 - Intro:
    - Introducing the Tools
    - Before We Start - get lab environment up and running
    - How to setup Ansible AVD in Arista Test Drive environment
    - Prepare Github Codespaces Environment
    - Run AVD Playbooks
    - Make Some Changes in AVD Repository
  - Section 2 - Ansible and Git 101
  - Section 3 - Common AVD provisioning cases
- Make a break when you see a slide with a coffee cup ☕
- Ask questions at any time!

# What is NOT covered in this Workshop?

- This workshop is not a deep dive into each and every topic. It is covering some advanced concepts, but you may need additional documentation and training to understand every topic in details.

For additional information please refer to the following resources:

- [Ansible AVD Documentation](#)
- [VSCode Documentation](#)
- [Git Documentation](#) - Pro Git book is a good start
- Container Trainings by [@jpetazzo](#):
  - [Github repository](#)
  - [Training materials](#)
- We are not going to use Arista CloudVision Portal (CVP) in this workshop. It provides a lot of advantages, but is not essential to understand the concepts covered in this workshop.
- If you will not find something you expect in this workshop, there can be 2 reasons:
  - It is not covered in this workshop
  - It is waiting for your contribution to this repository! 

## Requirements

- You **MUST** have a Github account !  
Register [here](#).
- You **MUST** have an [arista.com](#) account  
to download cEOS-lab image for  
Codespaces.

# References

- If you are not using ATD, the functionality of this repository will rely on many amazing open source projects:
  - [ContainerLab](#)
  - [VSCode](#)
  - [DevContainers](#)
  - [Marp](#)
  - [Excalidraw VSCode](#)
- This repository is also relying on following free/commercial Github features:
  - [Github Actions](#)
  - [Github Pages](#)
  - [Github Codespaces](#)
- All photos are taken from [Pexels](#) and [Unsplash](#). Excellent free stock photos resources. It's not possible to reference every author individually, but their work is highly appreciated.

# Additional Arista Workshops

- Check following workshops for additional information:
  - [ATD-AVD Workshop](#)
  - [Arista CI Workshops](#)

# Introducing The Tools

## Section 1.1

- The bird view on the tools we are going to use in this workshop.
- No details, they will come in a later sections. Just and overview.

# What is Git?

- **In Short:**

Git is a distributed version control system that tracks changes to a set of files and enables collaborative work.

- **Fun Fact:**

Git was created by Linus Torvalds in 2005 to develop Linux kernel.

git

# What is GitHub?

- GitHub is a Git repository hosting platform.
- Allows to coordinate multiple local copies of the same repository and more.

# VSCode

- Visual Studio Code is an extensible source-code editor developed by Microsoft and free to use.
- This will be our main tool to work with Ansible AVD and interact with Git repositories in the workshop and production.
- We are not going to cover VSCode installation and customization in this workshop. Check [VSCode documentation](#) for details.

# Before We Start

## Section 1.2

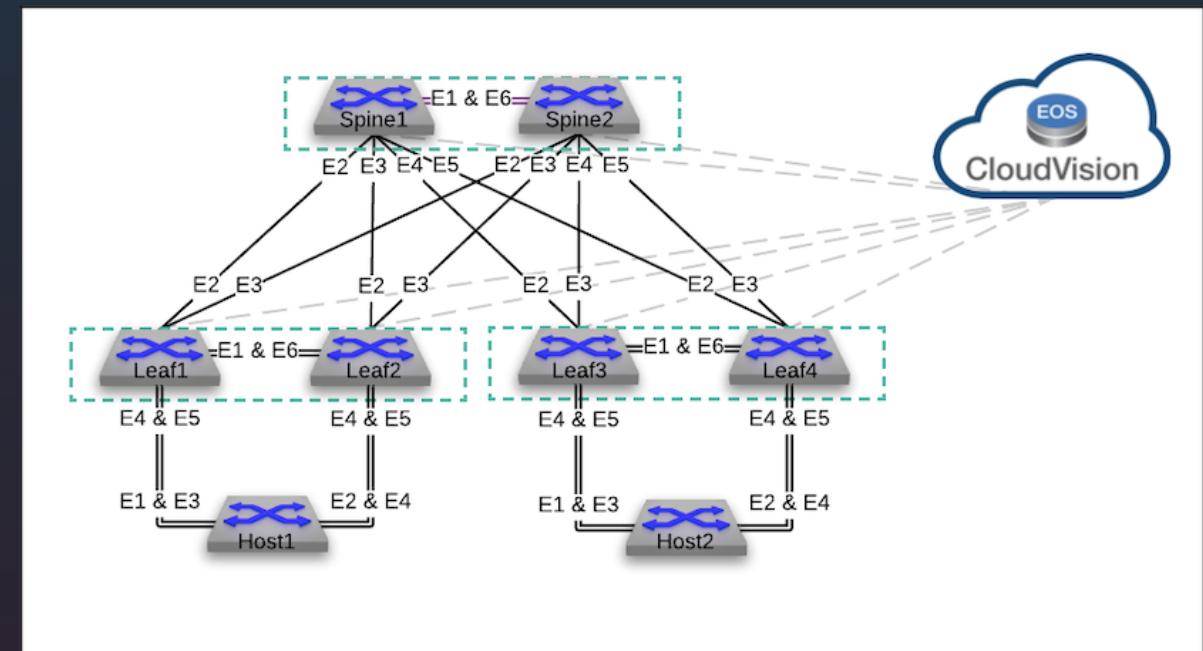

- How to get your lab environment up and running

# How to use this Workshop?

- To try all practical examples you need to have access to the lab environment. There are 3 possible options:
  - Use Github Codespaces. This is the preferred option, but double check that you understand all the costs and free tier limits.
  - Use Arista Test Drive - Single DC topology. Please ask your Arista SE to create an ATD lab for you.
  - Build your own lab environment: Ubuntu LTS + Docker + ContainerLab. This option is not described in detail, but the devcontainer used to build Codespaces environment will work on any machine with Docker installed. Please contact your SE if you need help.

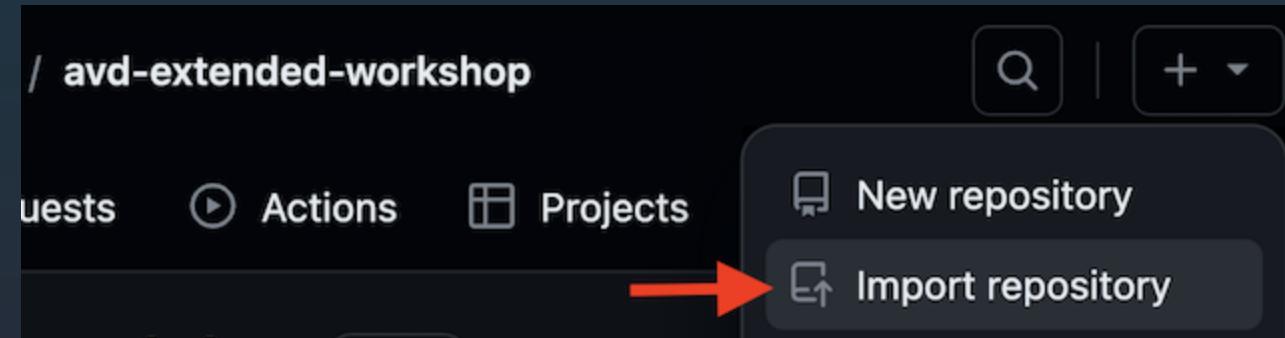

# Lab Topology

- This workshop is using Arista Test Drive Single DC topology.
- To match minimize resources and fit default Codespaces 4-core machine, the topology was reduced by removing leaf3, leaf4, host1 and host2.
- Feel free to adjust Ansible inventory and group variables if you are using ATD lab and would prefer to activate them all. But it's not essential for this workshop.
- CVP is not used as it's not required for this workshop.

# Github Repository Import

- Create a copy of this repository on your Github account. That will allow you to make any changes without impacting the original repository.
- Alternatively you can fork this repository, but in this case you must **NOT** ( ! ) open any pull requests to the original repository.
- To make a copy of the repository click  button in the top right corner of the Github page and select **Import repository** option.

# Github Repository Import, Step 2

- Enter the following URL in `Your Old Repository's Clone URL` field:
  - `https://github.com/arista-netdevops-community/avd-extended-workshop`
- Use your own account in `Owner` field and `avd-extended-workshop` or another name in the `Repository Name` field.
- Create `Public` repository. That will simplify interaction with this repo and allow use of Github free features.
- Wait until the import is completed.
- Your clone will now be referenced as `<your-copy-of-this-repository>` in this workshop.

## Import your project to GitHub

Import all the files, including revision history, from another version control system.

Required fields are marked with an asterisk (\*).

Support for importing Mercurial, Subversion and Team Foundation Version Control (TFVC) repositories will end on October 17, 2023. For more details, see the [changelog](#).

### Your old repository's clone URL \*

`https://github.com/arista-netdevops-community/avd-extended-workshop`

Learn more about the types of [supported VCS](#).

### Your new repository details

Owner \*

ankudinov

Repository name \*

/ same-or-another-name

same-or-another-name is available.

Public

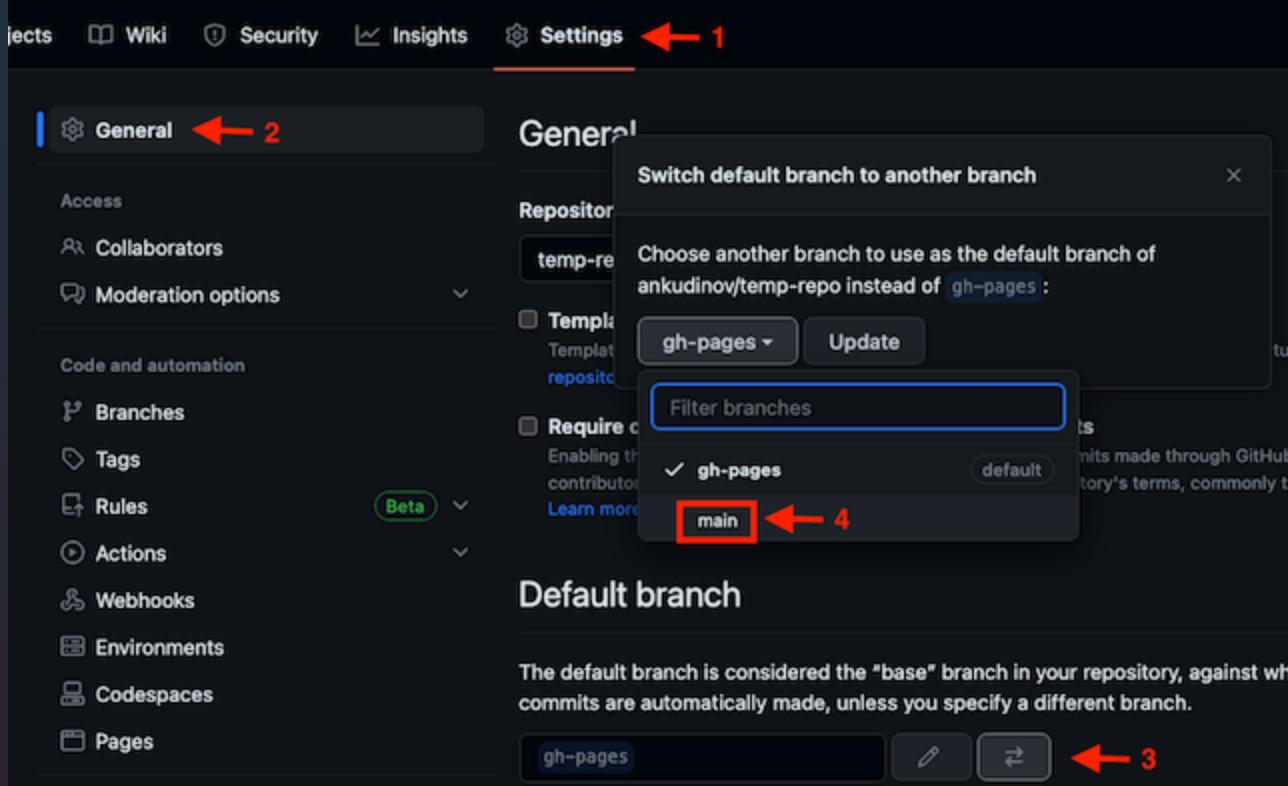

Anyone on the internet can see this repository. You choose who can commit.

Private

You choose who can see and commit to this repository.

# Github Repository Import, Step 3

- Confirm that `main` is the default Git branch after the import.
- Click `Settings` tab in the top right corner of the Github page.
- Click `General` on the left panel.
- Scroll down to `Default branch` section, click `Switch to another branch` button and select `main` branch.
- All set! 🎉

# How to Setup ATD Environment

## Section 1.3

- skip hands on in this section if you are using Codespaces
- still read the slides as they explain AVD installation process

# How to setup Ansible AVD in Arista Test Drive environment?

- We could use a script to setup required Ansible collections and tools in Arista Test Drive environment, but it's a good opportunity to discuss what are the requirements but installing them manually.
- For details please check [AVD documentation](#) Installation > Collection Installation section.

# Open Programmability IDE

- Use the lab token provided by Arista representative to access the lab environment.
- Check the status of the lab environment. If it's **Shutdown** - click **Start** button.
- Click **Programmability IDE** button to open VSCode in the browser:
  - To access **Programmability IDE** use the password listed on the starting Web page.
  - The VSCode functionality in the Web browser is provided by **ATD Code server container**
- Click **Yes, I trust the authors** button to continue. 
- Open new terminal in VSCode: **Top Left Corner (3 parallel lines) > Terminal > New Terminal**

Your topology is currently: **Shutdown** 1

Access Topology: [Click Here to Access Topology](#)

Topology Address: Topology Shutdown

Time Remaining: 00:00:00

Deployment Date: 30/06/2023, 13:41:00

Termination Date: 07/07/2023, 13:41:00

2

SUBMIT

# Install Ansible AVD

```
# 1. Update package index files
sudo apt-get update

# 2. Install iutils as life is hard without ping
sudo apt-get install -y --no-install-recommends iutils-ping

# 3. Add .local/bin in home folder to PATH
export PATH=$PATH:/home/coder/.local/bin

# 4. Upgrade pip and install Ansible core
#     If you get errors, ignore. This bug will be fixed soon.
pip install --upgrade pip
pip3 install "ansible-core>=2.13.1,<2.14.0"

# 5. Install Arista AVD collection
ansible-galaxy collection install arista.avd==4.1.0

# 6. Install AVD collection requirements
pip3 install -r /home/coder/.ansible/collections/ansible_collections/arista/avd/requirements.txt
```

For additional details check Arista Ansible AVD [Collection installation docs](#).

# Ansible Installation Warnings

- Double check that the path to Ansible collection is correct. Normally it is expected to be in  
`/home/coder/.ansible/`
- You `PATH` environment variable must be set correctly!
- Never install Ansible as root user!
- Watch out for environments with a long history, conflicting Python installations etc.
- Containers make it simple! Use containers! 🐳  
The Codespaces environment is based on a container with all requirements installed.

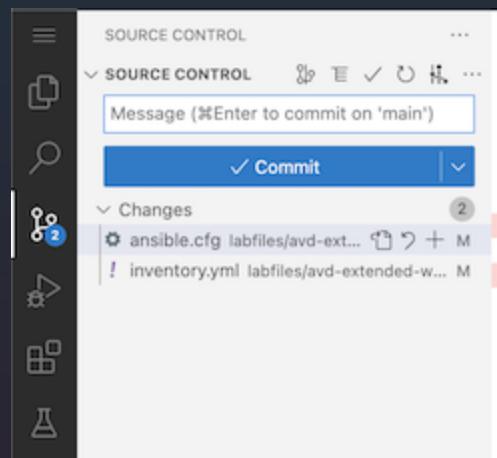

# Setup Ansible AVD Repository

```
# 1. install yq to adjust AVD yaml files - https://github.com/mikefarah/yq
#     you can certainly edit yaml files manually, but there would be no fun 🤦
export VERSION="v4.34.1" BINARY="yq_linux_amd64"
sudo wget https://github.com/mikefarah/yq/releases/download/$VERSION/$BINARY -O /usr/bin/yq \
    && sudo chmod +x /usr/bin/yq
# 2. Clone your copy of this repository
cd labfiles
git clone https://github.com/<gh-handle>/<your-copy-of-this-repository>.git avd-extended-workshop
# 3. switch to the repository directory
cd avd-extended-workshop
# 4. confirm that you are working with the `main` branch
#     if not, type following command to change the branch
git checkout main
#     you should see the following prompt
#     avd-extended-workshop git:(main)
# 5. update ansible.cfg to match ATD container user
cp extras/ansible-avd.cfg avd_inventory/ansible.cfg
# 6. set Ansible password to your AVD environment password
yq -i '.all.vars.ansible_password = "<your-password>"' avd_inventory/inventory.yml
```

# Commit Changes to Git

- Click VSCode **Source Control** icon in the left panel.
- Click **+** button to stage all changes. Alternatively you can accept VSCode suggestion to do that automatically every time by selecting **Always** option.
- Enter a *meaningful* commit message in the **Message** field.
- Click **Commit** button.

The screenshot shows the VSCode interface with the Source Control sidebar open. The 'Changes' section lists two files: 'ansible.cfg' and 'inventory.yml'. Both files have a '+' icon next to them, indicating they are staged for commit. A message input field at the top says 'Message (Enter to commit on 'main')' with a blue 'Commit' button below it. To the right, a diff view shows the contents of 'ansible.cfg' with several changes highlighted in red and green, such as 'filter\_plugins' being moved from one path to another.

```
1 [defaults]
2 host_key_checking = False
3 inventory = inventory.yml
4 gathering = explicit
5 retry_files_enabled = False
6- filter_plugins = /home/vscode/ans →
7 roles_path = roles
8- collections_paths = /home/vscode/ →
9 jinja2_extensions = jinja2.ext.l
10 interpreter_python = /bin/python3
11
12 [persistent_connection]
13 connect_timeout = 120
14 command_timeout = 120
15
```

# Prepare Github Codespaces Environment

## Section 1.4

- you can skip this section if you are using ATD lab
- still read the slides as they explain how to use Codespaces

# Before You Create Codespaces Environment

- Codespaces is a paid feature. Please check [Github Codespaces pricing](#)
- It has a free tier for personal accounts:
  - 120 core-hours per month -> will be 30 hours on a 4-core machine
  - 15 GB storage per month -> this will be a bottleneck for the workshop container image
- The free tier is enough to complete this workshop, but don't forget to delete the Codespaces environment after the workshop.
- Check `your account > Settings > Billing and plans > Spending limits` to make sure that if you exceed the limit, there will be no charges. The default limit of `0.00` will avoid any extra expenses.

## Billing & plans / Monthly spending limits

Set up a monthly spending limit. You can adjust it at any time. [Read more information about spending limits.](#)

### Actions & Packages

#### Limit spending

Set up a spending limit on a monthly basis

\$ 0,00

Update limit

Leaving it at \$0.00 will avoid any extra expenses

#### Unlimited spending

Pay as much as needed to keep Actions & Packages running

### Email alerts

Receive email notifications when usage reaches 75%, 90% and 100% thresholds.

Included resources alerts

Spending limit alerts

### Codespaces

#### Limit spending

Set up a spending limit on a monthly basis

\$ 0,00

Update limit

Leaving it at \$0.00 will avoid any extra expenses

#### Unlimited spending

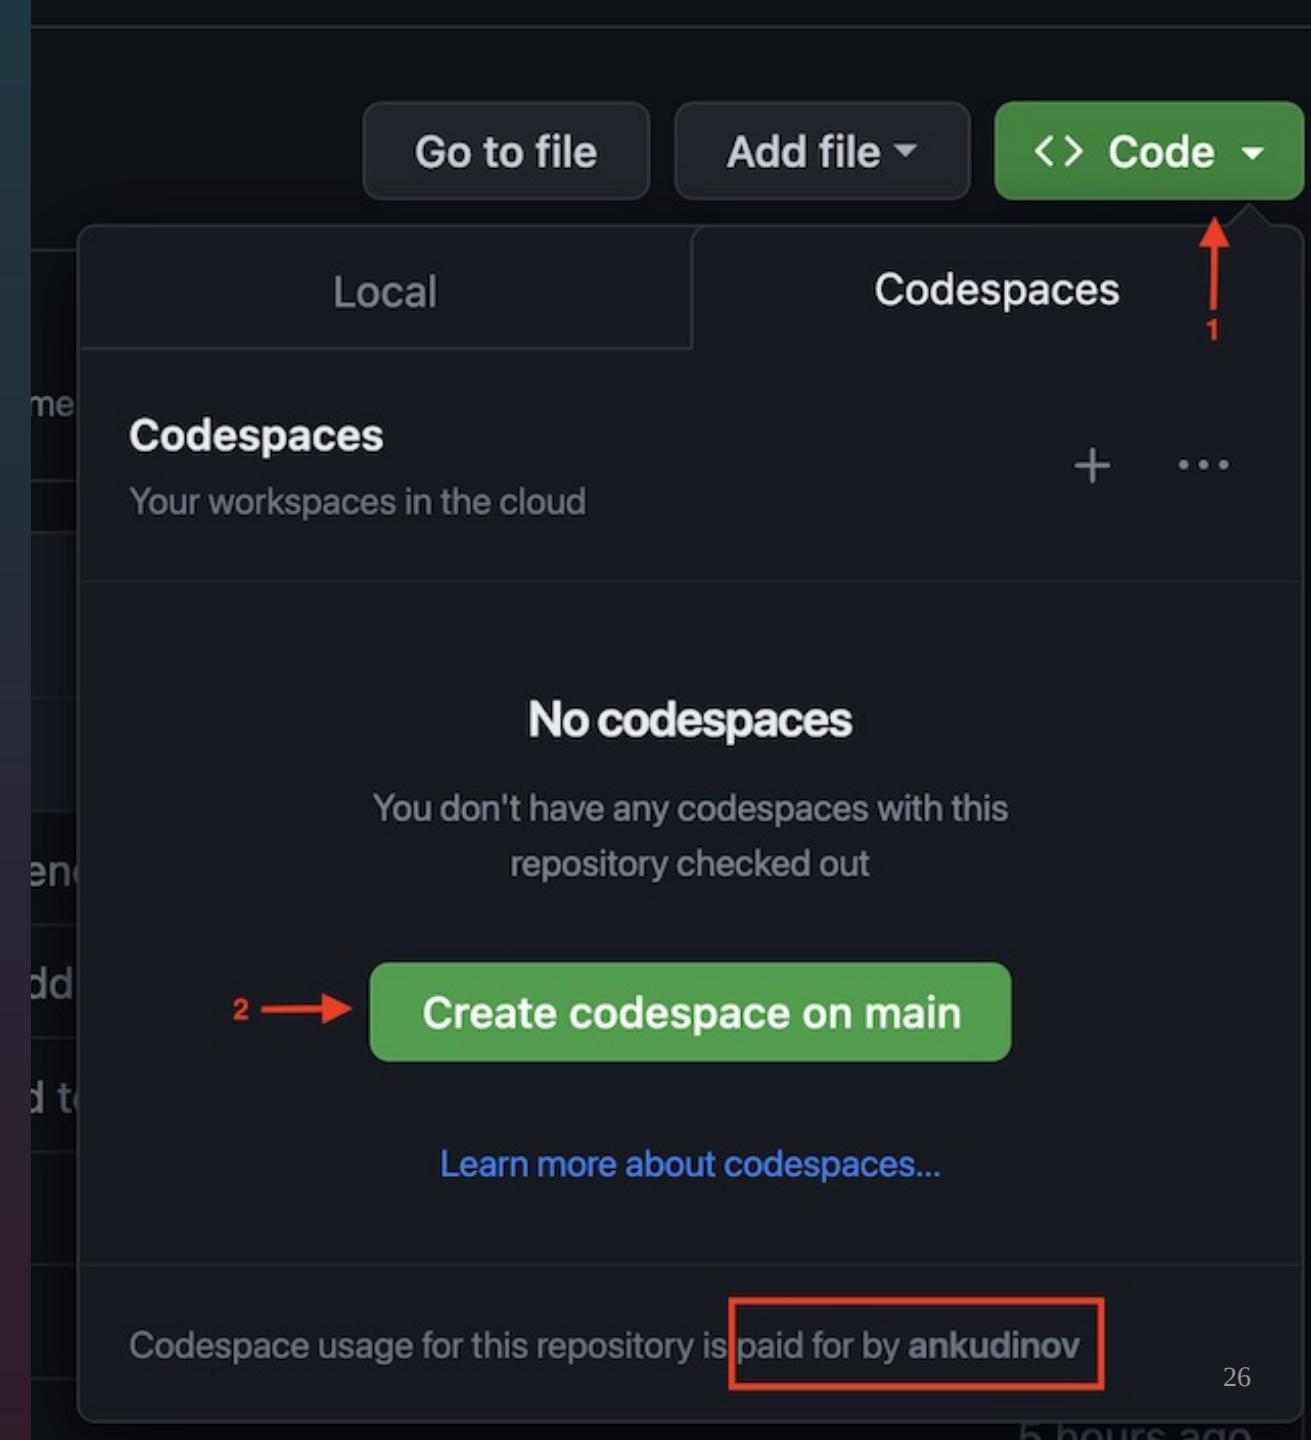

Pay as much as needed to keep Codespaces running

# Start a Codespace

- Click **Code** button in the top right corner of the Github page.
- Click **Create codespace on main** button.
- Wait until the codespace environment is created.
- Once codespace container is ready the VSCode will open automatically in your browser.

**WARNING ! :**

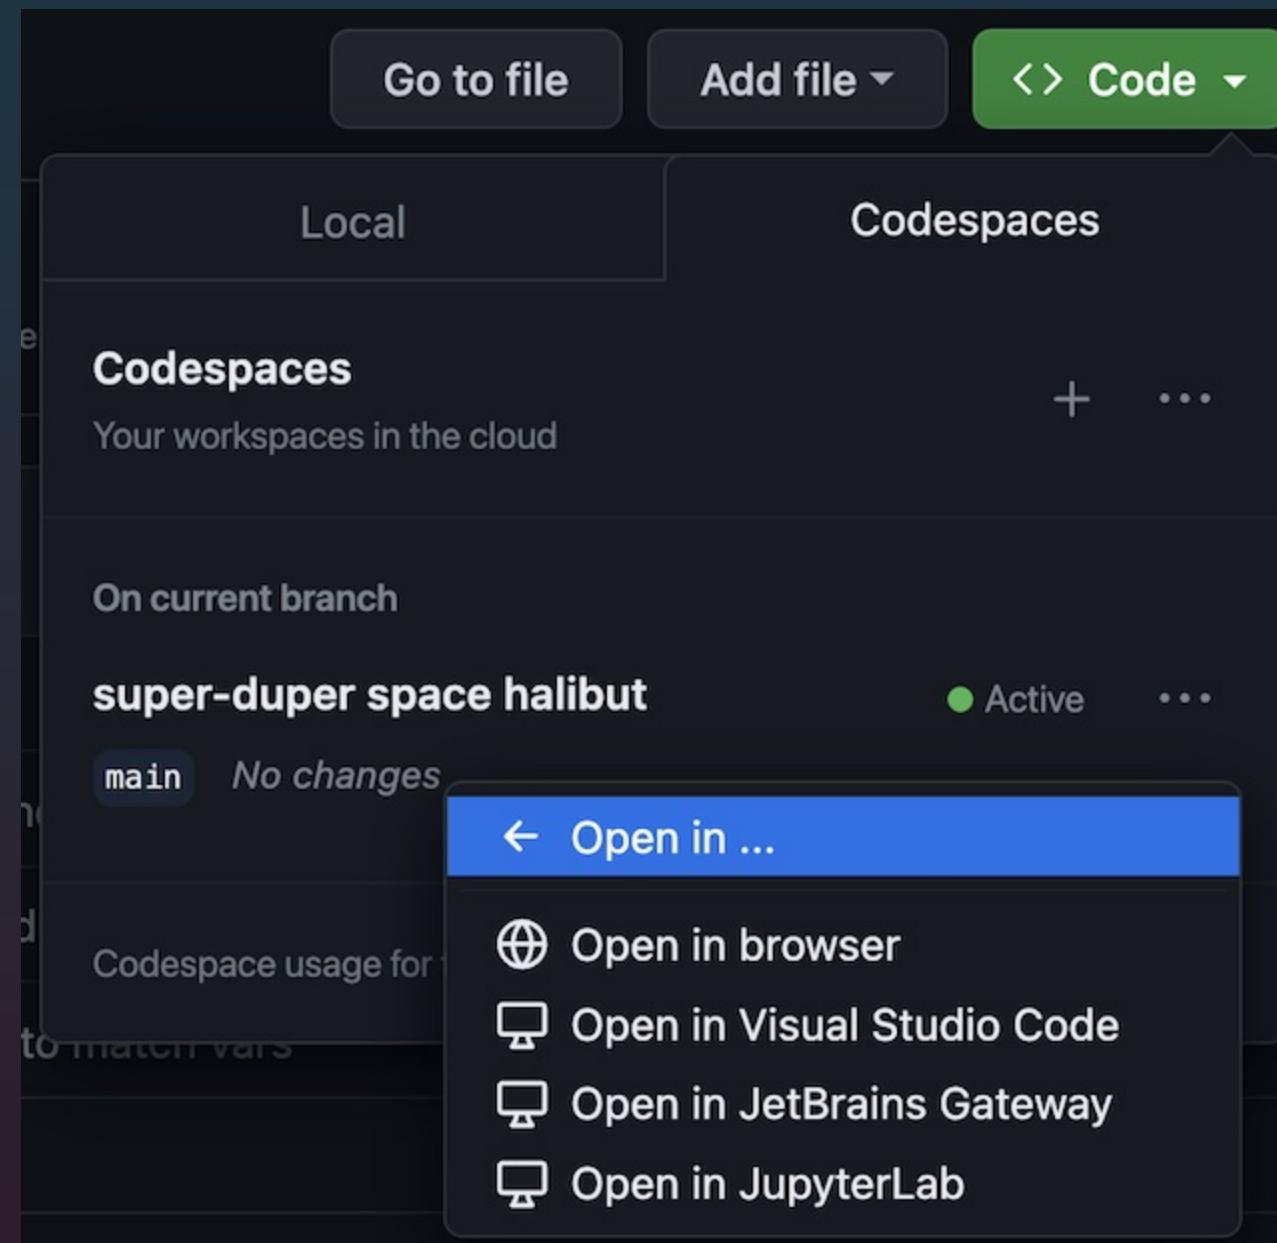

- Check **paid for by** field and make sure that you are using your personal account. If you are using a company account, you may be charged for the Codespaces usage. Also double-check previous slide and make sure that you understand the costs and limits.
- Do not use pre-builds. They consume storage across regions and can quickly exceed the free tier limit.

# Open Existing Codespace

- Once the Codespace is created, you can open it again by clicking `Code` button in the top right corner of the Github page and clicking 3 dots next to codespace name.
- Alternatively you can open it from the [Github Codespaces page](#)
- If you have VSCode installed locally, pick `open in Visual Studio Code` option. Otherwise use `Open in browser` option. The codespace container will always run remotely.

**WARNING !** : Do not forget to delete the Codespace after the workshop.

# Using Codespaces Container

- Codespaces container is ready to use.
- All required tools and dependencies are already installed. Check `ansible-galaxy collection list` output to confirm.
- Nevertheless:
  - The ContainerLab topology must be started and stopped manually.
  - cLab requires cEOS image to be uploaded first.

```
👉 Welcome to Codespaces! You are on a custom image defined in your devcontainer.json file.  
💡 To explore VS Code to its fullest, search using the Command Palette (Cmd/Ctrl + Shift + P)  
📝 Edit away, then run your build command to see your code running in the browser.  
@ankudinov □ /workspaces/temp-repo (main) $ ansible-galaxy collection list  
  
# /home/vscode/.ansible/collections/ansible_collections  
Collection      Version  
-----  
ansible.netcommon 5.1.1  
ansible.utils     2.10.3

rel. notes: https://containerlab.dev/rn/0.37/#0371
```

# Uploading cEOS Image

- The cEOS image is not included in the Codespaces container and must be uploaded manually.
- 1st, download the image from [Arista Software Download Center](#). Go to cEOS-lab section and download the image. Latest 4.29 image is recommended.
- To upload the image to the Codespaces container [GitHub CLI](#) must be used:
  - To install GitHub CLI go to:  
<https://cli.github.com/>
  - Check [GH CLI installation instructions](#) for additional details.
- GitHub CLI allows you to control your Github account from the command line. Including Github Codespaces.

```
pa@pa ~
$ gh codespace --help
Connect to and manage codespaces

USAGE
  gh codespace [flags]

AVAILABLE COMMANDS
  code:      Open a codespace in Visual Studio Code
  cp:        Copy files between local and remote file systems
  create:    Create a codespace
  delete:   Delete codespaces
  edit:     Edit a codespace
  jupyter:  Open a codespace in JupyterLab
  list:     List codespaces
  logs:    Access codespace logs
  ports:   List ports in a codespace
  rebuild: Rebuild a codespace
  ssh:     SSH into a codespace
  stop:    Stop a running codespace
  view:   View details about a codespace

INHERITED FLAGS
  --help   Show help for command

LEARN MORE
  Use 'gh <command> <subcommand> --help' for more information about a command.
  Read the manual at https://cli.github.com/manual
```

# Configure GitHub CLI

```
# 1. Follow https://github.com/cli/cli#installation instructions to install GH CLI
# 2. Authenticate with GH CLI
gh auth login
#   Select `GitHub.com` option and pick `Login with a web browser`
#   Follow the instructions to login to your Github account
# 3. Authenticate with Codespaces
gh auth refresh -h github.com -s codespace
# follow the instructions
# 4. Check that you can access Codespaces
gh codespace list
# 5. Confirm that you can SSH to your codespace
gh codespace ssh
#   Pick the codespace you want to connect to
# 6. While connected to the codespace via SSH create a directory to upload cEOS image
#   The directory name must be listed in .gitignore to avoid committing the image to the repository
<your-codespace-in-ssh> (main) $ mkdir .gitignored
# 7. Exit SSH session
<your-codespace-in-ssh> (main) $ exit
# 8. Upload cEOS image to the Codespaces container
gh codespace cp <path-to-ceos-image> -c <your-codespace-name> remote:/workspaces/avd-extended-workshop/.gitignored
```

# Import cEOS Image and Start cLab Topology

- Open VSCode terminal and run the following command to import cEOS-lab image:

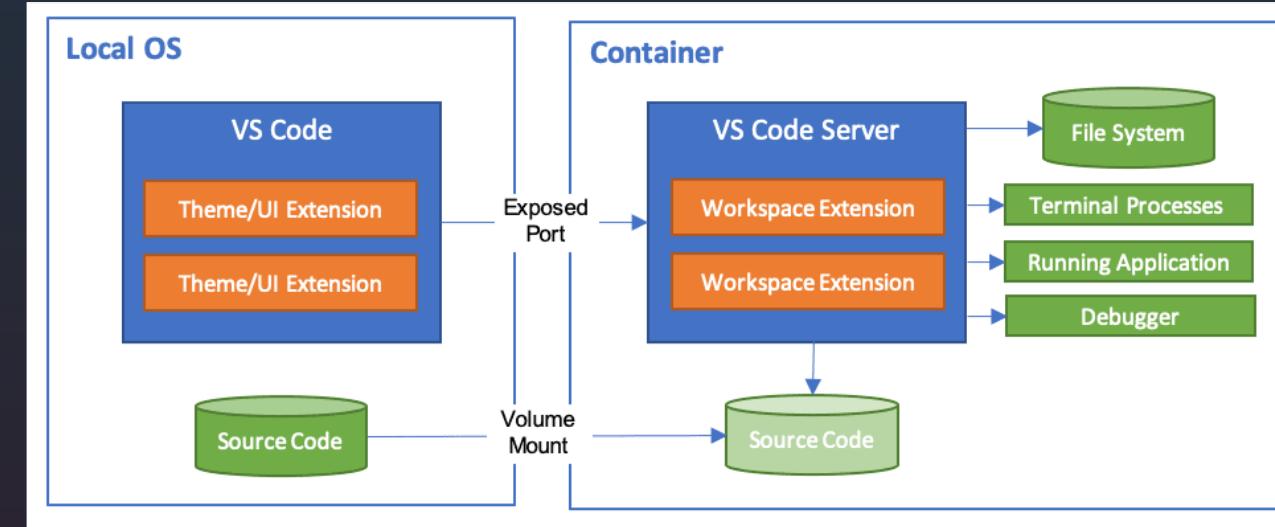

```
docker import .gitignored/<ceos-image-name> ceos-lab:latest
```

- Start cLab topology: `make start`
- To stop the lab use `make stop` at any time.
- If codespace is deactivated by timeout - redeploy the lab.

```
@ankudinov □ /workspaces/temp-repo (main) $ sudo clab inspect -t clab/topology.clab.yml

# Use The Local VSCode and Dev Container

- It's possible to run exactly the same container locally on a machine with Docker installed and use local VSCode Remote Containers feature to connect to it.
- Obviously there are no charges for this option. It's completely free, except the electricity bill.
- It is not covered in this workshop for one single reason: there are too many different environments and it's impossible to cover them all.
- Check [VSCode Dev Containers documentation](#) for details.

## Coffee Break ☕

5 min

# Run AVD Playbooks

## Section 1.5

- Just build an EVPN network with Ansible AVD and enjoy the result!

# What is Ansible AVD?

- AVD stands for Arista Validated Design
- Documentation is available at [avd.arista.com](http://avd.arista.com)
- Historically it is based on the [EVPN Deployment Guide](#), but now it's much more advanced and developing fast.
- Ansible AVD repository is available here: [github.com/aristanetworks/ansible-avd](https://github.com/aristanetworks/ansible-avd)
- The Ansible AVD collection is relying on:
  - [EOS foundational modules](#) maintained by RedHat: `ansible-galaxy collection install arista.eos`
  - [Ansible CVP modules](#) to interact with CloudVision Portal when required

# Typical Ansible AVD Automation Workflow

- Collect user input from various data sources and aggregate in a single source of truth. For ex. git repository.
- Generate low level variables from abstracted input data using sophisticated fabric logic
- Parse Jinja2 templates to produce plain text configs
- Push plain text configs via CloudVision Portal as change-control "proxy" or directly to devices via eAPI.

# AVD Collection Structure

- Ansible AVD consists of the following key roles:
  - `eos_designs`  - an set of modules to produce low level variables from abstracted input data using sophisticated fabric logic
  - `eos_cli_config_gen`  - generate Arista EOS cli configuration from a set of templates and variables produced by  `eos_designs`  role
  - `eos_validate_state`  - validate operational state of Arista EOS devices
  - `cvp_configlet_upload`  - upload configlets to CloudVision Portal
  - `eos_configlet_deploy_cvp`  - deploy configlets to Arista EOS devices via CloudVision Portal

# Run Ansible AVD Playbooks

```
# 1. switch to AVD inventory directory
#   on ATD:
cd ~/project/labfiles/avd-extended-workshop/avd_inventory
#   on Codespaces:
cd /workspaces/avd-extended-workshop/avd_inventory
# 2. run ansible-playbook to generate configs
#   wait until the playbook will finish execution and check the configs in avd_inventory/intended/configs
ansible-playbook playbooks/atd-fabric-build.yml
# 3. run ansible-playbook to push configs to devices
ansible-playbook playbooks/atd-fabric-provision-eapi.yml
# 4. Done! 🎉 Click on on any lab switch and check `show bgp evpn summary`
```

Playbook execution example:

```
o avd_inventory git:(main) ✘ ansible-playbook playbooks/atd-fabric-provision-eapi.yml
PLAY [Deploy Configs] *****
PLAY [arista.avd.eos_config_deploy_eapi : Verify Requirements] *****
AVD version 4.1.0
Use -v for details.
ok: [spine1 -> localhost]

TASK [arista.avd.eos_config_deploy_eapi : Create required output directoyes if not present] *****

changed: [spine1]
changed: [leaf1]
changed: [leaf2]

PLAY RECAP *****
leaf1           : ok=2    changed=2    unreachable=0    failed=0    skipped=0    rescued=0    ignored=0
leaf2           : ok=2    changed=2    unreachable=0    failed=0    skipped=0    rescued=0    ignored=0
spine1          : ok=4    changed=3    unreachable=0    failed=0    skipped=0    rescued=0    ignored=0
```

# Useful eAPI Troubleshooting Trick

If you are facing any issues when to push configs or collect any data using eAPI, test access with the following command:

```
curl --user <login>:<password> --data "show version" --insecure https://<switch-mgmt-ip>:443/command-api --verbose
```

Try it now! 🔨

With `--verbose` it can tell you a lot.

# Make Some Changes in AVD Repository

## Section 1.6

- Change underlay routing protocol
- Add new tenant
- Filter VLANs
- Connect endpoints
- Validate the network

# Change Underlay Routing Protocol to OSPF

- Go to `avd_inventory/group_vars/ATD_FABRIC.yml` and uncomment following line:

```
underlay_routing_protocol: ospf
```

- Run `ansible-playbook playbooks/atd-fabric-build.yml` to generate new configs.
- Click `Source Control` icon on the left panel and check the diffs.
- Commit your change with a meaningful commit message.
- (Optional): Run `ansible-playbook playbooks/atd-fabric-provision-eapi.yml` to push the new configs to the lab switches.

# Add New Tenant

- The `Tenant` in AVD is an abstraction combining a set of VRFs, VLANs and SVIs to be created on a set of switches.
- Open `avd_inventory/group_vars/ATD_TENANTS_NETWORKS.yml` and uncomment the lines related to `Tenant_B`
- Run `ansible-playbook playbooks/atd-fabric-build.yml` to generate new configs.
- This will generate required EVPN configs for the new VRF, VLANs and SVIs.
- Click `Source Control` icon on the left panel and check the diffs.
- Commit your change with a meaningful commit message.
- (Optional): Run `ansible-playbook playbooks/atd-fabric-provision-eapi.yml` to push the new configs to the lab switches.

```
tenants:  
  # Tenant_A data will be present above Tenant_B  
  # keep it unchanged  
  - name: Tenant_B  
    mac_vrf_vni_base: 20000  
    vrf:  
      - name: Tenant_B_OP_Zone  
        vrf_vni: 20  
        svis:  
          - id: 210  
            name: Tenant_B_OP_Zone_1  
            tags: ['opzone']  
            profile: WITH_NO_MTU  
            ip_address_virtual: 10.2.10.1/24  
          - id: 211  
            name: Tenant_B_OP_Zone_2  
            tags: ['opzone']  
            profile: GENERIC_FULL  
            ip_address_virtual: 10.2.11.1/24
```

# Filter VLANs Deployed

- Currently all VLANs listed in `AVD_TENANTS_NETWORKS.yml` are deployed on the switches even if there are no client-facing interfaces configured for those VLANs.
- To filter out unused VLANs, open `avd_inventory/group_vars/ATD_FABRIC.yml` and uncomment the following line:

```
l3leaf:  
  defaults:  
    # ... other defaults  
    # keep all the lines above unchanged  
    # ...  
    filter:  
      only_vlans_in_use: true
```

- Run `ansible-playbook playbooks/atd-fabric-build.yml` to generate new configs.
- Click `Source Control` icon on the left panel and check the diffs.
- Commit your change with a meaningful commit message.
- (Optional): Run `ansible-playbook playbooks/atd-fabric-provision-eapi.yml` to push the new configs to the lab switches.

# Change The Port Configuration

- Currently ports to `host1` are configured as access ports in VLAN110.
- Let's change that to a trunk with VLANs 110 and 160 allowed.
- Open `avd_inventory/group_vars/ATD_SERVERS.yml` and add a new port profile. The change is shown on the right.
- Run `ansible-playbook playbooks/atd-fabric-build.yml` to generate new configs.
- Click `Source Control` icon on the left panel and check the diffs.
- Commit your change with a meaningful commit message.
- (Optional): Run `ansible-playbook playbooks/atd-fabric-provision-eapi.yml` to push the new configs to the lab switches.

```
vscode □ /workspaces/avd-extended-workshop/avd_inventory (main) $ git diff
diff --git a/avd_inventory/group_vars/ATD_SERVERS.yml b/avd_inventory/group_vars/ATD_SERVERS.yml

# Validate The Network

- To confirm that network state is correct use AVD network validation role.
- 1st, make sure that you have generated the latest configs and pushed them to the switches:

```
ansible-playbook playbooks/atd-fabric-build.yml  
ansible-playbook playbooks/atd-fabric-provision-eapi.yml
```

- Run the following command to validate the network state:

```
ansible-playbook playbooks/atd-validate-state.yml
```

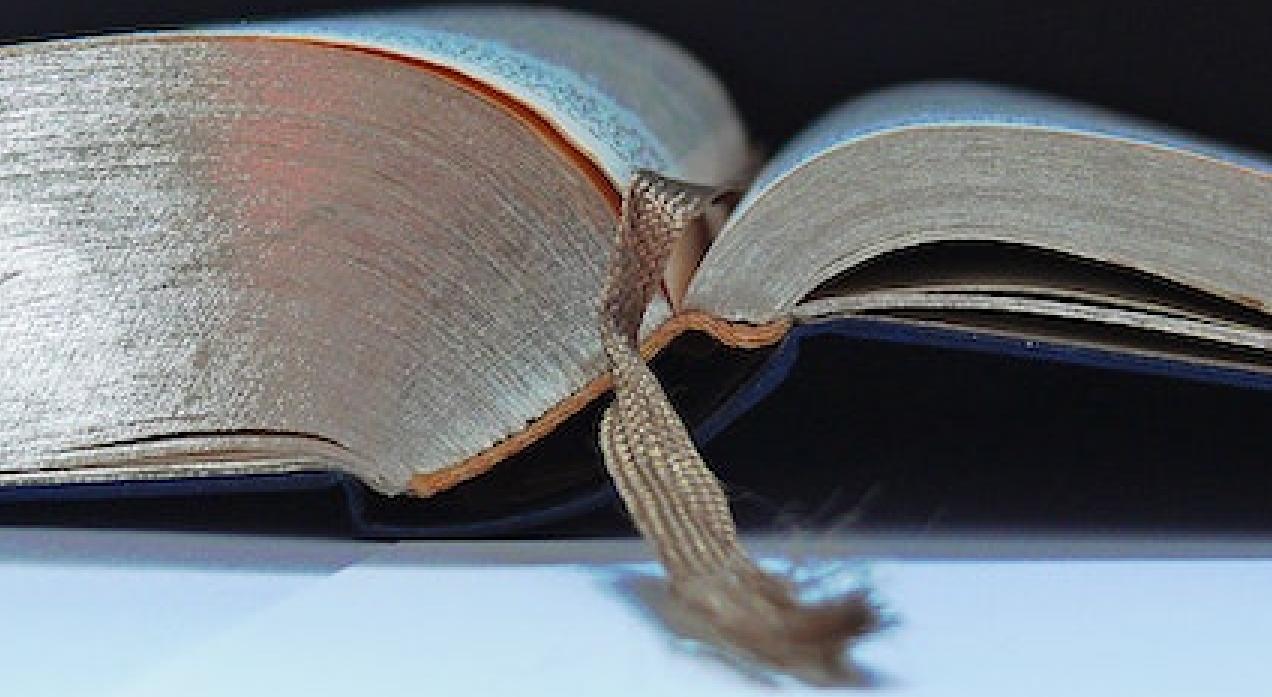

- The validate role has some limitations that are quite critical when building a CI pipeline. But there is some work in progress. For example, check [ANTA library](#) for an alternative solution.

## End of Section 1

Questions?

- Start section 2 when ready

# YAML

## Section 2.1

- A few words about YAML

# What is YAML?

- YAML is a data serialization language.
- It is not the only one. There are many others: JSON, XML, TOML,INI, CSV etc.
- Purpose:
  - convert data to a machine-readable format that can be stored or transmitted.
- YAML is generally considered to be a human-readable format. Well, kind of. 😎 But at least it's possible to add comments, which is not possible in JSON.
- YAML is the default format to write Ansible playbooks, inventory files and group/host variables.

The playbook used to generate configs for this workshop in YAML format:

```
```yaml
---
- name: Manage Arista EOS EVPN/VXLAN Configuration
  hosts: ATD_FABRIC
  connection: local
  gather_facts: false
  collections:
    - arista.avd
  vars:
    fabric_dir_name: "{{fabric_name}}"
    execute_tasks: false
  tasks:
    - name: Generate intended variables
      import_role:
        name: eos_designs

    - name: Generate device intended config and documentation
      import_role:
        name: eos_cli_config_gen
```

# JSON and XML Examples

ATD KVM virtual machine specification in XML:

```
arista@devbox:~$ sudo virsh dumpxml cvp1
setlocale: No such file or directory
<domain type='kvm' id='1'>
  <name>cvp1</name>
  <uuid>4675315f-0b93-4798-8598-37d876666df9</uuid>
  <memory unit='KiB'>33554432</memory>
  <currentMemory unit='KiB'>33554432</currentMemory>
  <vcpu placement='static'>24</vcpu>
  <resource>
    <partition>/machine</partition>
  </resource>
  <os>
    <type arch='x86_64' machine='pc-i440fx-rhel7.0.0'>hvm</type>
    <boot dev='hd' />
  </os>
...
...
```

Right code sample is not native JSON format!  
JSON is not allowing comments as it is only focused on machine readability.  
JSONC is a JSON with comments. It is not a standard, but it is supported by many tools.

The devcontainer specification powering this workshop:

```
{
  "name": "avd_extended_workshop",
  "build": {
    "dockerfile": "Dockerfile",
    "args": {
      "_AVD_VERSION": "4.1.0",
      "_CLAB_VERSION": "0.37.1"
    }
  },
  "features": [
    "ghcr.io/devcontainers/features/docker-in-docker:1": {
      "version": "latest"
    },
    // add sshd to support gh cli codespace cp
    "ghcr.io/devcontainers/features/sshd:1": {
      "version": "latest"
    }
  ],
  // set minimum host requirements for cLab
  "hostRequirements": {
    "cpus": 4,
    "memory": "8gb",
    "storage": "32gb"
  }
}
```

# YAML Linter

- Linter is a tool that checks the code/document for errors, bugs, style violations etc.
- Install YAML-linter on your machine: `pip install --user yamllint`
- Create a minimalistic YAML file: `echo -n "key: value" > test.yaml`
- Run the linter to check errors:

```
vscode □ /workspaces/avd-extended-workshop (main) $ yamllint test.yaml
test.yaml
1:1      warning  missing document start "---"  (document-start)
1:11     error    no new line character at the end of file  (new-line-at-end-of-file)
```

- Congrats! 🎉 We have two errors in a single line YAML. 😬
- Linters are helpful! Always check your YAMLs with a CLI linter or VSCode/other IDE extension.

# Every YAML Starts with `---`

- Absolutely every YAML file must start with `---` on the first line.
- YAMLs without `---` are not valid, but will be accepted by many tools in fact.
- Quote from [yaml.org](#):

YAML uses three dashes ("---") to separate directives from document content. This also serves to signal the start of a document if no directives are present. Three dots ("...") indicate the end of a document without starting a new one, for use in communication channels.

- Another `---` in the same yaml file would indicate the start of a new document. It is not used in Ansible data structures normally.
- Every YAML file must end with an empty line.

There are many more rules in YAML that are rarely in use, but must be ~~100%~~ respected.

# JSON vs YAML for Ansible

- Ansible can accept variables in JSON format as well.
- Convert a group var file to JSON with `yq`

```
yq --prettyPrint -o=json avd_inventory/group_vars/ATD_SERVERS.yml > avd_inventory/group_vars/ATD_SERVERS.json
```

- Delete the YAML file and run the build playbook:

```
ansible-playbook playbooks/atd-fabric-build.yml
```

- New configs will be generated successfully. JSON is faster, YAML is still easier to read and edit at scale.
- Rollback the change once you test it.

# YAML Scalars, Mappings and Sequences

- YAML allows writing comments after `#`. Always add comments!
- YAML smallest building block is called `scalar`. That can be integer, string, boolean etc.

```
#  
key: "value"  
#      ^  
# this is a scalar
```

- The data can be defined in YAML as `mappings` (aka dictionaries)

```
a_key: a_value  
another_key: another_value  
nested:  
    sub_key: sub_value
```

- Or `sequences` (aka lists):

```
- item1  
- item2  
- item3
```

- Sequences can be defined in a single line as well and used in conjunction with mappings:

```
values: [ value1, value2, value3 ]
```

# Quote All The Strings

- A wisdom from the unknown source:

Experienced YAML users quote all the strings.

- YAML is flexible and not forcing you to quote strings. But that is often causing weird problems.
- If not certain, quote the string!
- That is especially important when working with Ansible. As Ansible has its own way of interpreting certain YAML values.
- Use following to check yourself:

```
yq --prettyPrint -o=json <name-of-your-yaml-file>
```

Is this YAML correct?

```
port_channel:  
  mode: on
```

Yes, but it will break Ansible playbook execution as `on` and `yes` are converted to `True` by Ansible.

```
ERROR! [leaf1]: 'Validation Error: servers[0].adapters[0].port_channel.mode': True is not of type 'str'  
ERROR! [leaf1]: 'Validation Error: servers[0].adapters[0].port_channel.mode': 'True' is not one of ['active', 'passive', 'on']
```

Fun with YAML

```
string: "just a string"  
integer: 1234  
and_that_is_an_integer_too: 0xABCD  
float: 12.34  
version: "1.0" # is a string  
boolean: true  
# that's super weird, don't do that  
but_that_is_a_string: !!str True  
# there is a special `null` value for this case  
and_this_is_not_empty:  
a_better_null: ~
```

# YAML Advanced Features

- YAML has some advanced features. Try to avoid them unless it is absolutely necessary.
- Example: anchors and aliases.
- Check [YAML specification](#) for details if interested.
- In AVD one advanced feature is used quite often. Multiline strings.

```
# a string with new lines and trailing spaces
string_with_new_lines: |
    This is a string
    with new lines
    and trailing spaces
# a string without new lines and with trailing spaces
string_without_new_lines: >
    This is a string
    without new lines
    and with trailing spaces
```

Result:

```
{
  "string_with_new_lines": "This is a string      \nwith new lines\nand trailing spaces",
  "string_without_new_lines": "This is a string      without new lines and with trailing spaces",
}
```

# Ansible

## Section 2.2

- Quick intro into essential Ansible concepts

# What is Ansible?

- Ansible is an open-source framework for automation and more.
- Ansible is agentless. That means it is not required to install any agent software on the target device. Some Ansible modules may still have dependencies that must be installed on the target device first.
- The most important Ansible components are:
  - Ansible Core - the core framework
  - Ansible Collections - a set of modules, plugins, roles and playbooks
  - Ansible Automation Controller (previously known as Ansible Tower) - a commercial product with a web UI and more

# Ansible Installation

- The minimum Ansible installation was covered in the previous section.
- Confirm that installation is correct by using following command:

```
vscode □ /workspaces/avd-extended-workshop/avd_inventory (main) $ ansible --version
ansible [core 2.13.10]
  config file = /workspaces/avd-extended-workshop/avd_inventory/ansible.cfg
  configured module search path = ['/home/vscode/.ansible/plugins/modules', '/usr/share/ansible/plugins/modules']
  ansible python module location = /home/vscode/.local/lib/python3.9/site-packages/ansible
  ansible collection location = /home/vscode/.ansible/collections/ansible_collections
  executable location = /home/vscode/.local/bin/ansible
  python version = 3.9.16 (main, Jan 23 2023, 23:35:25) [GCC 10.2.1 20210110]
  jinja version = 3.1.2
  libyaml = True
vscode □ /workspaces/avd-extended-workshop/avd_inventory (main) $ ansible-galaxy collection list

# /home/vscode/.ansible/collections/ansible_collections
Collection      Version
-----
ansible.netcommon 5.1.1
ansible.utils     2.10.3
arista.avd       4.1.0
arista.cvp       3.6.1
arista.eos       6.0.1
```

- Check versions, the path to collections, modules and executables, search path and ansible configuration file location.

# Ansible and Python

- Ansible is a Python-based framework.
- Make sure that you have correct Python version installed on your machine and all dependencies are in place.
- If you have multiple Python versions installed on your machine, make sure that you are using the correct one. Ideally use virtual environment or container.
- Few useful commands to check Python installation:

```
vscode □ /workspaces/avd-extended-workshop (main) $ which python3
/usr/local/bin/python3
vscode □ /workspaces/avd-extended-workshop (main) $ python3 --version
Python 3.9.16
vscode □ /workspaces/avd-extended-workshop (main) $ pip3 freeze
ansible-core==2.13.10
attrs==23.1.0
bcrypt==4.0.1
certifi==2023.5.7
cffi==1.15.1
charset-normalizer==3.1.0
cryptography==41.0.1
cvprac==1.3.1
...
...
```

# Few Words about ansible.cfg

- `ansible.cfg` is required to configure Ansible correctly by defining following key parameters:
  - `inventory` - the path to the inventory file
  - `collections_paths` - the path to the collections
  - `interpreter_python` - the path to the Python interpreter
- Make sure that Ansible binary is able to find the path to the `ansible.cfg` file. There are multiple ways to achieve that:
  - `ANSIBLE_CONFIG` environment variable
  - `ansible.cfg` file in the current directory
  - `~/.ansible.cfg` file in the user's home directory
  - `/etc/ansible/ansible.cfg` file
- Check the corresponding [documentation for details](#).
- In some CI (Continuous Integration) and cloud environments `ANSIBLE_CONFIG` is the only way to force Ansible to accept the existing `ansible.cfg` due to default permissions:

If Ansible were to load `ansible.cfg` from a world-writable current working directory, it would create a serious security risk. Another user could place their own config file there, designed to make Ansible run malicious code both locally and remotely, possibly with elevated privileges. For this reason, Ansible will not automatically load a config file from the current working directory if the directory is world-writable.

# Ansible Inventory

- Every Ansible project must also have an inventory file.
- Ansible inventory specifies how to reach hosts managed by Ansible.
- Hosts can be divided into groups and subgroups.
- `.ini` or YAML formats are accepted. We'll focus on YAML only as it's more flexible.
- `ansible-inventory` command displays the inventory and all relevant variables for specific host or group of hosts:

```
# try following commands
ansible-inventory --list
ansible-inventory --list --yaml
ansible-inventory --host <host>
```

```
---
all:
  # some variables can be define directly in the inventory file
  # but in most cases it is preferable to use host_vars and group_vars
  vars:
    # set login credentials
    # use Ansible vault, env vars, etc. for sensitive data instead
    ansible_user: arista
    ansible_password: arista
    # set the default network OS for all hosts to find corresponding Ansible collection
    ansible_network_os: arista.eos.eos
    # configure privilege escalation
    ansible_become: true
    ansible_become_method: enable
    # set Ansible connection parameters according to the collection documentation
    ansible_connection: httpapi
    ansible_httpapi_port: 443
    ansible_httpapi_use_ssl: true
    ansible_httpapi_validate_certs: false
    # set Python interpreter to be used
    ansible_python_interpreter: $(which python3)

children:
  # Ansible group name

    children:
      ATD_LEAFS:
        # apply group_vars/ATD_SERVERS.yml to all hosts in ATD_LEAFS group
        ATD_SERVERS:
          children:
            ATD_LEAFS:
```

# Ansible Add-hoc Commands

- Once the inventory is ready, we can start using Ansible.
- The most basic way to use Ansible is to run ad-hoc commands using `ansible` command to run specific module.

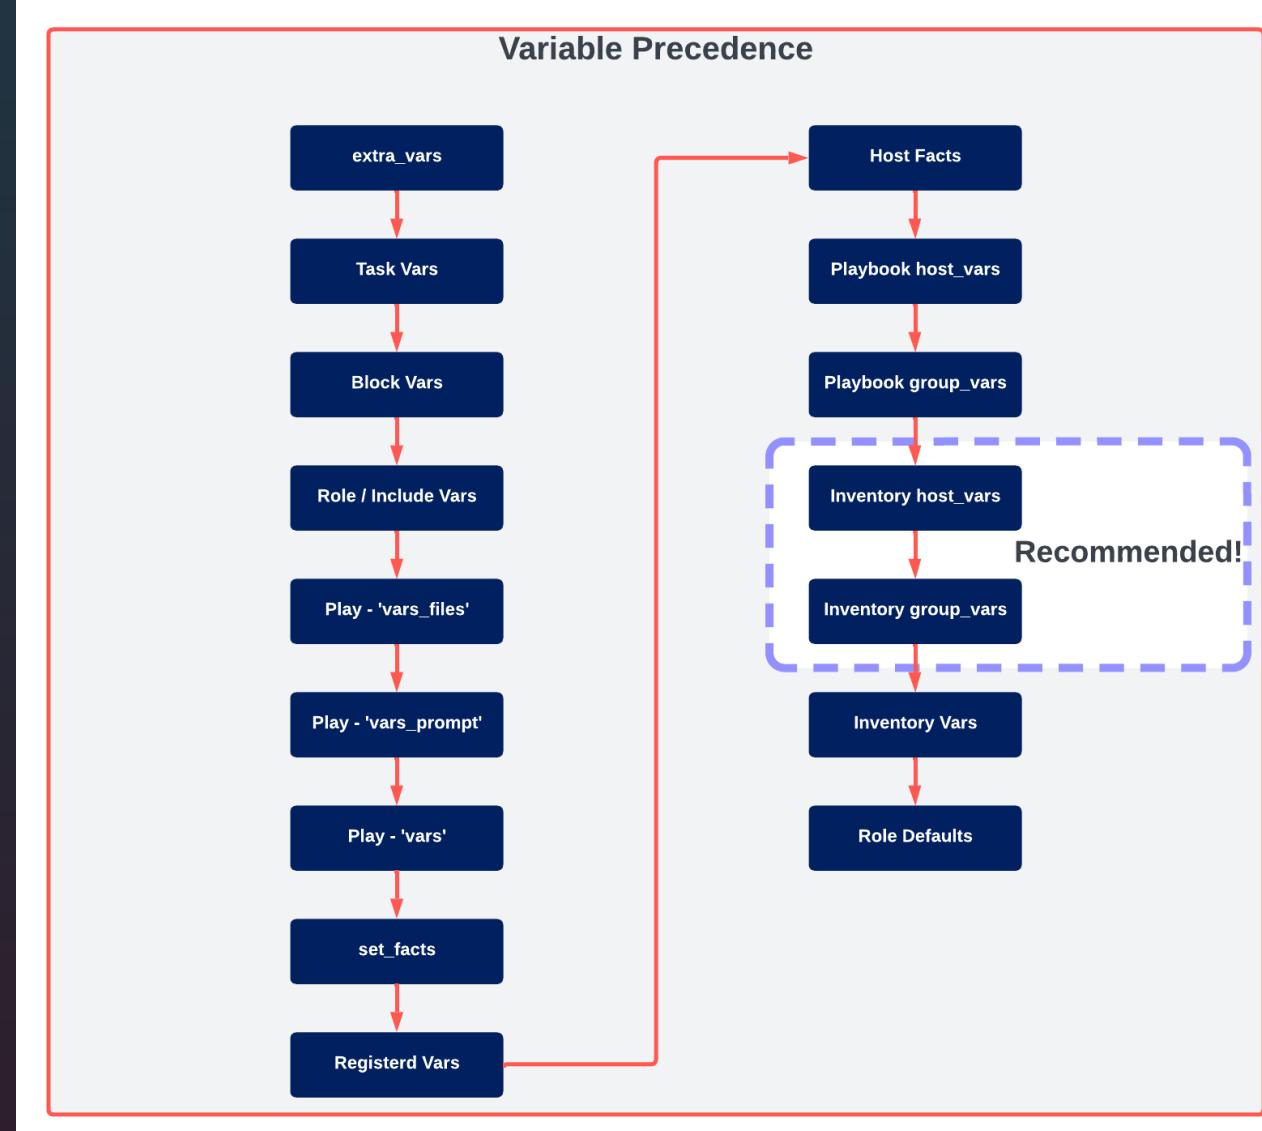

```
# check memory
ansible all -m shell -a "free -m"
#           ^- module name
ansible ATD_LEAFS -m shell -a "free -m"
#           ^- group name
```

# Beware of Ping Module

- Ansible `ansible.builtin.ping` module is not a real ICMP ping. 😊 It attempts to connect to the host and confirms that Python interpreter is available.
- `ping` module can fail on machines that are reachable but have no Python interpreter installed by default.
- `ping` module isn't working correctly with all connection methods. In particular it will not work with `ansible_network_os: arista.eos.eos` and `ansible_connection: httpapi`. The module will report success without errors even if the switches are not reachable.

# Ansible Variables

- Ansible variables can be defined in multiple places and can be used to build configurations, define what modules to run, etc.
- The variable precedence is defined by [Ansible documentation](#).
- We'll focus on group\_vars and host\_vars.

## Let's Define Some Ansible Variables

```
# set banner for all switches
yq -i ".banner_text = \"This banner came from group_vars/ATD_FABRIC.yml\"" avd_inventory/group_vars/ATD_FABRIC.yml
# set banner for leaf1
mkdir avd_inventory/host_vars/
touch avd_inventory/host_vars/leaf1.yml
yq -i ".banner_text = \"This banner came from host_vars/leaf1.yml\"" avd_inventory/host_vars/leaf1.yml
# confirm settings for leaf1 and leaf2
ansible-inventory --yaml --host leaf1 | grep banner
ansible-inventory --yaml --host leaf2 | grep banner
```

# Ansible Playbook

- Ansible playbook is a YAML file that defines a set of tasks to be executed on a set of hosts.
- A playbook consists of one or more `plays`.
- Every play consists of one or more `tasks` using specific `modules` with or without parameters.
- `banner_login` is not the most useful module, but it's a good example to start with.
- Create the playbook  
`avd_inventory/playbooks/deploy_banner.yml`
- Do not run the playbook! We'll do that later.
- Module behind the scenes:
  - `arista.eos`
  - `arista.eos.eos_banner`

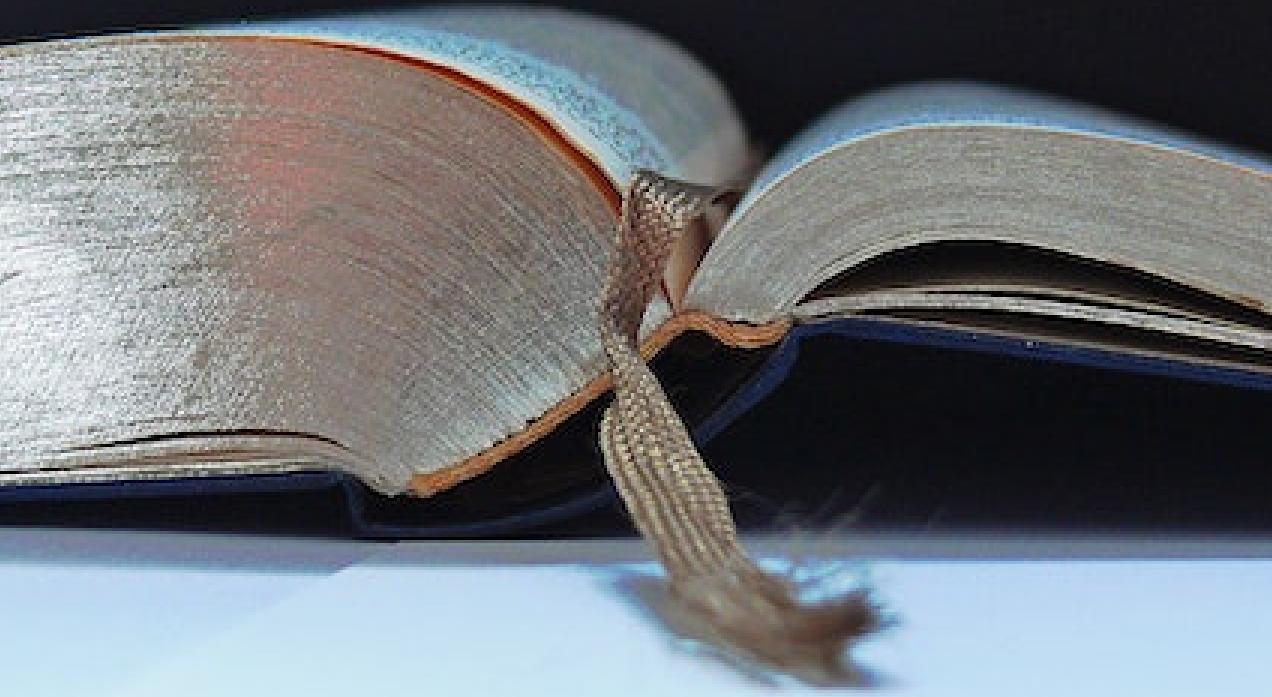

```
---
```

```
# a playbook to configure banner on EOS switches
- name: Configure banner on EOS switches # <-- Play
  hosts: ATD_FABRIC # <-- Target hosts
  tasks:
    - name: Gather facts # <-- Task
      arista.eos.eos_facts: # <-- Module
        gather_subset: all # <-- Module parameter
        register: facts
    - name: Check facts output
      debug:
        msg: "{{ facts }}"
    - name: Configure login banner
      arista.eos.eos_banner:
        banner: motd
        text: |
          "{{ banner_text }}"
        state: present
```

# Ansible Playbook Arguments

- `ansible-playbook` command has number of useful arguments that can be used to control the execution.
- We'll highlight few of them:
  - `--check` - run the playbook in check mode. No changes will be applied.
  - `--diff` - show the diff of the changes that will be applied.
  - `--limit` - limit the execution to specific hosts or groups.
  - `--tags` - limit the execution to the tasks with specific tags.
  - `--forks` - limit the number of parallel tasks, default is 5.
  - `--verbose` - increase the verbosity level. Up to -vvvvv. Helps to troubleshoot the playbook execution. But not a lot.  
😊
- Now run the following command:

```
cd avd_inventory
ansible-playbook playbooks/deploy_banner.yml --check --diff --limit leaf1 -vvv
```

# Git

## Section 2.3

- Git for AVD users

# Recap

- As we discussed before:
  - | Git is a distributed version control system that tracks changes to a set of files and enables collaborative work.
- We have already cloned the workshop repository and made some changes. Delete it and clone it again to start fresh:

```
cd labfiles
git clone https://github.com/<gh-handle>/<your-copy-of-this-repository>.git avd-extended-workshop
git checkout main
```

- On Codespaces it's enough to delete the old codespace and create a new one.
- Get you Git Cheat Sheet copy [here](#).

# Setup Git

- Git is already pre-installed in the container.
- Setup your name and email address:

```
git config --global user.name "<first-and-2nd-name>"  
git config --global user.email "<your-email>"
```

- Check the current configuration:

```
git config --list
```

- To edit the configuration file:

```
# usually the config file is located in ~/.gitconfig  
git config --global --edit
```

# Git Status and origin/main

- `git status` provides some info about the current state of the repository.

```
vscode □ /workspaces/avd-extended-workshop (main) $ git status
On branch main
Your branch is ahead of 'origin/main' by 1 commit.
  (use "git push" to publish your local commits)

nothing to commit, working tree clean
```

- `Origin` is the default name for the remote repository from where the local copy was cloned. `origin/main` is the remote twin of our main branch.

# Git Branches

- Branch is technically a pointer to a specific commit.
- Branching allows to work on multiple features in parallel without other branches being affected.
- `git branch` command lists all branches in the repository.
- You can switch between branches with `git checkout <branch-name>` when there are no uncommitted changes.
- `Trunk` is another name for the default branch (also called `Master` or `Main`). If required you can change the default branch name.

```
# change the default branch name to main  
git config --global init.defaultBranch main
```

# Branch Naming Convention

- You can name your branches in any way. But it's better to have a naming convention from the start.
- Branch naming convention is a set of rules that describes how branches should be named.
- This simplifies collaboration, reviews and CI pipelines.
- Some common branch naming prefixes are listed below:
  - `feature/` - a branch that is used to work on some new features or changes
  - `fix/` - a branch that is used to fix a bug or implement a workaround. Normally it corresponds to an issue. This can be further divided into
    - `bugfix/` - planned bug fixes
    - `hotfix/` - urgent bug fixes, may lack planning
    - `docsfix/` - fixes in the documentation
  - `refactor/` - a branch that is used to refactor/optimize the code
  - `docs/` - for documentation changes
  - `test/` - a temporary branch used for testing only and normally not merged anywhere
  - `release/` - a special branch that is used to prepare a release
- The full branch name normally looks like `<prefix>/<description>` or `prefix_description`.
- Use any convention that works, but be consistent!

# Git Branching Strategy

- A branching strategy is a convention that describes when and how branches are created, merged and deleted.
- It's essential to keep stable and predictable Git repository state.
- There are many branching strategies:
  - [Gitflow](#)
  - [Trunk-based development](#)
  - [GitHub flow](#)
  - [GitLab flow](#)
  - [Feature Branch](#)
  - etc.
- Our strategy in this workshop will be extremely simple:
  - Pull the latest changes from the origin.
  - Create a new feature branch named `feat/<description>`.
  - Make changes and commit them.
  - Push the changes to the origin.
  - Create a pull request to merge the changes to the main branch.
  - Delete the feature branch after the pull request is merged.
  - (Optional): Create release branch and deploy the change in the lab.

# Create New Branch

- Create a new branch and build switch configs:

```
# create a new branch
git branch feat/init_network
# switch to the new branch
git checkout feat/init_network
# build switch configuration files with AVD
cd avd_inventory/ && ansible-playbook playbooks/atd-fabric-build.yml
# check the status
git status
```

- There will be some untracked and uncommitted files.

```
@ankudinov □ /workspaces/avd-extended-workshop/avd_inventory (feat/init_network) $ git status
On branch feat/init_network
Untracked files:
  (use "git add <file>..." to include in what will be committed)
    documentation/
    intended/
nothing added to commit but untracked files present (use "git add" to track)
```

# Add New Files to Git

- To add files to Git use `git add <file-name>` or `git add .` to add all files in the current directory.

```
@ankudinov □ /workspaces/avd-extended-workshop/avd_inventory (feat/init_network) $ git add .
@ankudinov □ /workspaces/avd-extended-workshop/avd_inventory (feat/init_network) $ git status
On branch feat/init_network
Changes to be committed:
  (use "git restore --staged <file>..." to unstage)
    new file:  documentation/ATD_FABRIC/ATD_FABRIC-documentation.md
    new file:  documentation/ATD_FABRIC/ATD_FABRIC-p2p-links.csv
    new file:  documentation/ATD_FABRIC/ATD_FABRIC-topology.csv
    new file:  documentation/devices/leaf1.md

```

- If you are using VScode GUI, you can configure VSCode to add new files automatically.

# Git Diff

- The files we added are now `staged` according to Git terminology.
- Before you commit the changes, check the diff:

```
git diff --staged
```

- If we are not happy with the changes for some reason, we can discard them:

```
git reset --hard  
# or  
# reset and delete files and directories  
git reset  
git clean -fd
```

# Git Commit

- Commit the changes:

```
@ankudinov □ /workspaces/avd-extended-workshop/avd_inventory (feat/init_network) $ git commit -m "feat: init network configuration"

```

# Back In Time

- You can check the diff between any 2 commits:

```
git diff a49eab9630c90a99fcde3eff0f2e37a450e81d33 74e80fb401498ae628626f9b2d42fa3db1871ded
```

- To check the diff between the current commit and the previous one:

```
git diff HEAD^ HEAD
```

- To rollback the changes before you push them to the remote:

```
git reset --hard HEAD^
```

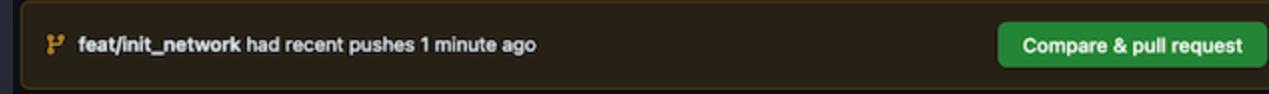

- Or simply use a commit ID.

# Push the Changes to the Remote

- To push the new branch to the remote, execute following command:

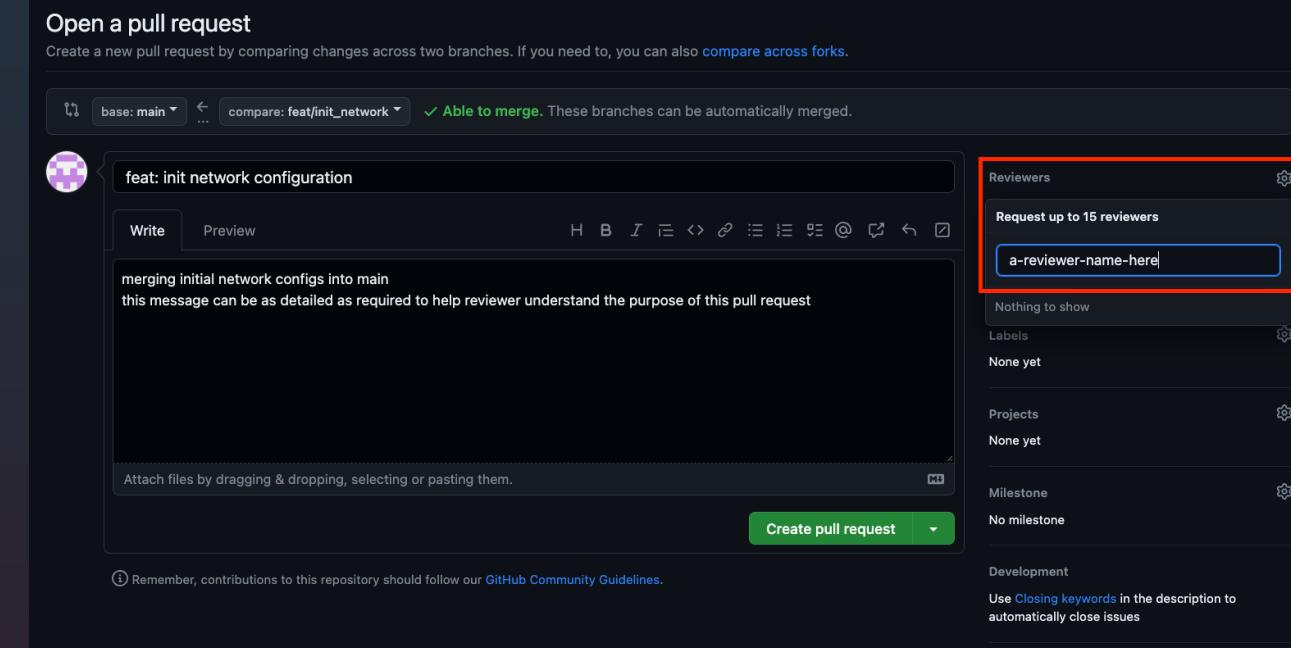

```
git push --set-upstream origin feat/init_network
```

- set-upstream is required to set the remote branch as the default branch for the local branch. VSCode will set it automatically.
- At this point, if you are using ATD or your own machine, you may be asked to authenticate. Please follow the steps documented in the [Arista CI workshop](#) to create a token and authenticate.  
-If the push was successful, the Compare and Pull button must be present on top of your Github repository web page. Click it.

# Open Pull Request

- Open a pull request window will appear.
- Add a meaningful message to help reviewers understand the purpose of the PR.
- Assign a reviewer if you have any. Talk to your workshop peers.
- Click Create pull request button.

## PR Review

- Click **Files changed** tab and review the configs generated by AVD and other files.
- When ready, switch back to **Conversation**

```

- This will bring your local repository in sync with the remote again.

# When Things Go Wrong

- If the PR was broken and reviewer have not noticed that, there are few options:
  - Switch back to the last stable branch.
  - Create a fix and open a new PR.
  - Inspect `git log` and use `git revert -m 1 <commit-id>` to revert the commit.
  - [Replace your branch with another one.](#)

```
# replacing main with a different branch to fix the trunk
git checkout main
git pull
git checkout <last-stable-branch>
git merge -s ours main
git checkout main
git merge <last-stable-branch>
```

## End of Section 2

Questions?

- to-be-continued

## Section 3

### Common AVD Provisioning Cases

- How to use your AVD repository efficiently

# Makefile and Containers

## Section 3.1

- A Few Words About Makefile
- How to use containers with AVD

# Makefile

- If you need a deeper dive into Makefile syntax and use case - the [makefiletutorial.com](http://makefiletutorial.com) is the best place to start. You'll be an expert in making Makefiles when you finish. 😎
- Originally Makefiles were used by C/C++ developers to compile the code.
- Makefiles have a few advantages that make them useful for other use cases:
  - They are simple.
  - They allow assigning a simple shortcut to complex actions.
  - They are available by default on most Linux distributions.
- We are going to use Makefile to create shortcuts to simplify AVD operations.

# Using Makefile Shortcuts

- Check that you are in the main workshop directory `avd-extended-workshop` where the Makefile is located:

```
vscode □ /workspaces/avd-extended-workshop (main) $ ls -la | grep Make
-rw-r--r-- 1 vscode vscode 1026 Jul 14 10:06 Makefile
```

- Inspect the Makefile syntax. Note the indent after a command. It's a tab, not spaces. Makefile is sensitive to that.
- Run `make help` command.

```
vscode □ /workspaces/avd-extended-workshop (main) $ make help
avd_build          Generate AVD configs
avd_diff           Show the diff between running config and designed config
avd_provision_eapi Deploy AVD configs using eAPI
help               Display help message
start              Deploy ceos lab
stop               Destroy ceos lab
```

- Test some shortcuts from the list. Makefile can simplify even more complex actions by hiding them behind a shortcut.

```
make run  # start the lab
make avd_build # build AVD configs
make avd_diff # check if the change is valid
make avd_provision_eapi # deploy the configs
make stop # stop the lab
```

# Docker

- This is not a Docker training and we are only going to cover containerized AVD use case.
- For additional information check [Introduction to Docker and Containers](#). It's great!
- Do not get confused by low level technical details if you are not familiar with Docker. Focus on higher level user experience.
- All examples from this workshop will work on Codespaces, but not ATD. Use [Play with Docker](#), your own machine with Docker or just follow the slides if you are not using Codespaces option.

# Why Containers for AVD?

- Building a stable AVD environment looks simple, but often much harder in reality as every system is very different.
- It's even harder to clone the same environment and experience for multiple users.
- Containers make it simple!

# Run cAVD

Running containerized AVD is simple.

```
# make a basic test to confirm docker functionality
docker run hello-world
# pull AVD container
# avd-all-in-one is a community repository and may be suboptimal in certain case
# you can always build your own image using Dockerfile based on the example from the repository
docker pull ghcr.io/arista-netdevops-community/avd-all-in-one-container/avd-all-in-one:latest
# run the container
make run  # <-- this hides quite a bit of Docker complexity, but easy to use
#           check the Makefile if you really want to know what happens behind the scenes
```

# AVD Container Warnings

- Do NOT run AVD container as root! That breaks all permissions and can create serious issues with your Git repository.
- Some RHEL-based distribution require exact match of UID inside and outside of the container. That requires a special intermediate image that will re-map the user ID or a sophisticated entrypoint. That is a dark magic and will not be covered in this workshop.
- Devcontainers make it even easier by solving the listed problems out of the box.

# Why Devcontainers?

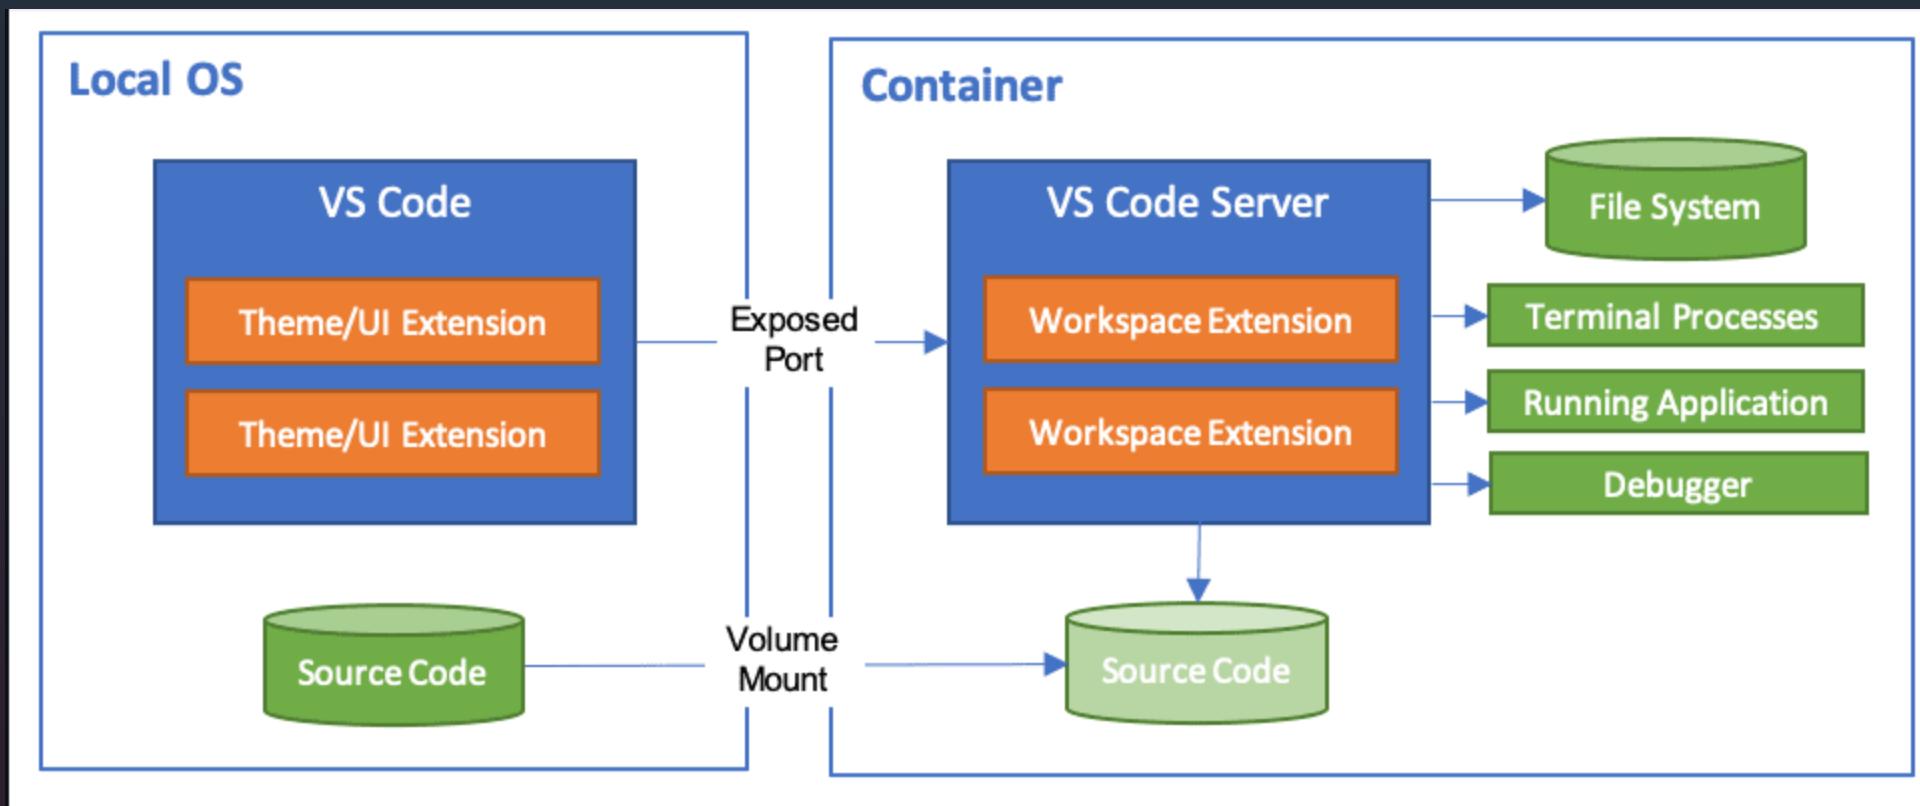

- Every project has dependencies.
- Managing dependencies is hard. Possible issues include, but not limited to: conflicting installations, system path, incorrect versions, etc.
- venv/pyenv and similar tools are often very specialized, provide limited isolation and do not cover all possible dependency issues. For ex. venv/pyenv cover Python only and can be easily broken.
- Containers provide a better way to build a stable environment, but learning barrier is higher.
- Devcontainers provide all advantages of containerized environments with additional advantages:
  - easy to build
  - easy to use
  - very portable
- Disadvantage: Devcontainers are a VSCode feature.

# Is It Hard to Build a Good Container?

- To build a reasonable container the following steps are usually required:
  - Craft a base Docker file with some essentials
  - Add non-root user, as root can break permissions in certain scenarios
  - The non-root user ID may not match user ID outside of the container. On some operating systems (for ex. RHEL and the family) that can be a serious problem. Find a way to map UID inside the container to the original UID. [Not a trivial task](#)
  - Create an [entrypoint](#). I'm certain everyone has a perfect understanding of this concept. 😊 Here is a relatively simple [example](#)
  - Take care of transferring your Git credentials, keys, etc. into the container if it was created as interactive
  - Think about security and something else that you'll certainly forget or never have time to start
  - ... and it has to be multi-platform
- Devcontainers are taking care of most of the points mentioned above out of the box  

# What is VScode Devcontainer?

A picture worth a thousand words. [Source](#).

# devcontainer.json

- `devcontainer.json` contains the specification for your devcontainer
- if `.devcontainer/devcontainer.json` is present in the directory, the VSCode will suggest to open the folder in the devcontainer automatically
- You can still use following commands when required:
  - Dev Containers: Open Folder in Container
  - Dev Containers: Rebuild Container
  - Dev Containers: Rebuild Container Without Cache
- A very short devcontainer specification can look like:

```
{  
  "name": "Python 3",  
  // it is possible to use `build` instead of image and provide Dockerfile  
  // pre-build image provides consistent results, but Dockerfile is easy to adjust for specific environment  
  "image": "mcr.microsoft.com/devcontainers/python:0-3.9"  
}
```

Check full `devcontainer.json` reference [here](#).

# Codespace is a Devcontainer

- Github Codespace for this workshop is based on a devcontainer feature.
- Inspect the [devcontainer.json](#) and [Dockefile](#) for details. All required dependencies like AVD and Containerlab are already part of the workshop container.
- Check `features` field in the `devcontainer.json`. That is a very effiecient way to add Docker-in-Docker and SSHD to the container without touching a single line in the Dockerfile.

```
"features": {  
    "ghcr.io/devcontainers/features/docker-in-docker:1": {  
        "version": "latest"  
    },  
    // add sshd to support gh cli codespace cp  
    "ghcr.io/devcontainers/features/sshd:1": {  
        "version": "latest"  
    }  
}
```

# What is Devcontainer Feature

Development container "Features" are self-contained, shareable units of installation code and dev container configuration. The name comes from the idea that referencing one of them allows you to quickly and easily add more tooling, runtime, or library "Features" into your development container for use by you or your collaborators.

- Short version: it's a script with a description doing some extra configuration when devcontainer is created
- You can create [your own features](#) using following structure:

```
+-- feature
|   +- devcontainer-feature.json
|   +- install.sh
|   +- (other files)
```

# Working with AVD Inventory

## Section 3.2

- How to work with AVD inventory efficiently and useful tricks

# Ansible Inventory for Multiple Networks

- Very often there is a need to build multiple networks with AVD. For example, multiple DCs or L3LS EVPN and L2LS management network.
- There are 2 possible options:
  - Create a dedicated repository for each network
  - Create a single repository for multiple networks
- Ansible repository is flexible and allows both options
- Both options are valid. Pick any according to your priorities.
- If a single inventory is used for multiple networks, create a dedicated Ansible group for each network segment and adjust playbooks accordingly.

```
...
# playbooks/avd-build-dc2.yml
- name: Build configs for DC2
  hosts: DC2_FABRIC
...
...
```

# Single vs Multiple Repositories

## Single Repository

- Advantages
  - Single source of truth to store all data
  - Allows sharing variables
  - Simple to maintain due to single point of control
  - No need to duplicate CI's, playbooks, Makefiles, etc.
  - "One ring to rule them all" concept. 🔮
- Disadvantages
  - Mistakes can have higher impact.
  - If the ring is burned, everything is gone. 💥

## Multiple Repositories Advantages

- Some structures are duplicated and overall can be more complex to maintain
- Mistakes are isolated and have lower impact
- Changes in one environment can not affect another environment directly

# Working with Big Data Structures in AVD

- Some data structures in AVD can be huge. Best example is port provisioning servers: can grow really fast in production.
- YAML with let's say 20K lines is not very human friendly.
- To simplify provisioning new servers, you can:
  - Split the port provisioning YAML into multiple files
  - Use some helper script/tools to work with complex data structures

# How to Split AVD Servers into Multiple Files

- Ansible allows splitting group vars into multiple files. For example ATD\_SERVERS group vars could be a directory:

```
ATD_SERVERS
| - main.yml
| - leaf1-servers.yml
| - leaf2-servers.yml
# ... etc
```

- The problem with this approach is that when Ansible will encounter the same key in different YAMLs, it will overwrite the value. That means if `server:` is defined everywhere only the last occurrence wins.
- AVD allows to define `connected_endpoints_keys:` that can be used to solve the problem above.

```
# avd_inventory/group_vars/ATD_SERVERS/main.yml
connected_endpoints_keys:
  leaf1-servers:
    type: server
  leaf2-servers:
    type: server
```

```
# avd_inventory/group_vars/ATD_SERVERS/leaf1-servers.yml
leaf1-servers:
  - name: host1
    <etc.>
```

# Use Script/Tools to Work with Complex Data

- We are only going to cover the most basic case here. In reality, there is no limit to custom code you can build on top of AVD.
- When building sophisticated tools, be sure you know how to support them in future.
- JSON usually is usually a better data format as an output for this option. But input data format can be anything.
- Let's do some basic tests with `yq` tool.
  - 1st, create following YAML file called `test.yml`:

```
---
```

```
servers:
- name: host2
  rack: pod1
  adapters:
    - switch_ports: [Ethernet12, Ethernet12]
      switches: [leaf1, leaf2]
      profile: TENANT_A
      port_channel:
        description: PortChannel
        mode: active
```

```
# inspect the result of merging 2 files
yq ea '. as $item ireduce "{}; . *+ $item "' avd_inventory/group_vars/ATD_SERVERS.yml test.yml
# update ATD_SERVERS.yml with an additional server
yq ea --inplace '. as $item ireduce "{}; . *+ $item "' avd_inventory/group_vars/ATD_SERVERS.yml test.yml
```

# Using `yq` to Add New Switches

- Now let's use `yq` tool to add new switches to `ATD_FABRIC.yml`
- Normally there is no need to do that as the corresponding data structure is simple. But it's a good example.
- Create `add_new_leaves.yml` with the following content:

```
---
l3leaf:
  node_groups:
    - group: pod2
      bgp_as: 65102
      nodes:
        - name: leaf3
          id: 3 # <-- yq will not number that automatically
          mgmt_ip: 192.168.0.14/24
          uplink_switch_interfaces: [Ethernet4, Ethernet4]
        - name: leaf4
          id: 4 # <-- yq will not number that automatically
          mgmt_ip: 192.168.0.15/24
          uplink_switch_interfaces: [Ethernet5, Ethernet5]
```

- Add data to `ATD_FABRIC.yml` and add switches to the `inventory.yml` manually or using `yq`:

```
yq ea --inplace '. as $item ireduce ({}; . *+ $item )' avd_inventory/group_vars/ATD_FABRIC.yml add_new_leaves.yml
```

# eos\_cli

- Sometimes there is a need to add plain text config to the configuration generated by AVD as a temporary workaround or to overcome some AVD limitations.
- `eos_cli`  key can be used to accomplish that.
- Inspect  `ATD_LAB.yml` . You'll find the following line of text:

```
 eos_cli: |-
    username arista privilege 15 role network-admin secret {{ ansible_password }}
```

- Note the use of Ansible variable  `ansible_password`  inside the string.
- Very often plain text configuration is unique to a device and therefore defined in  `host_vars` .

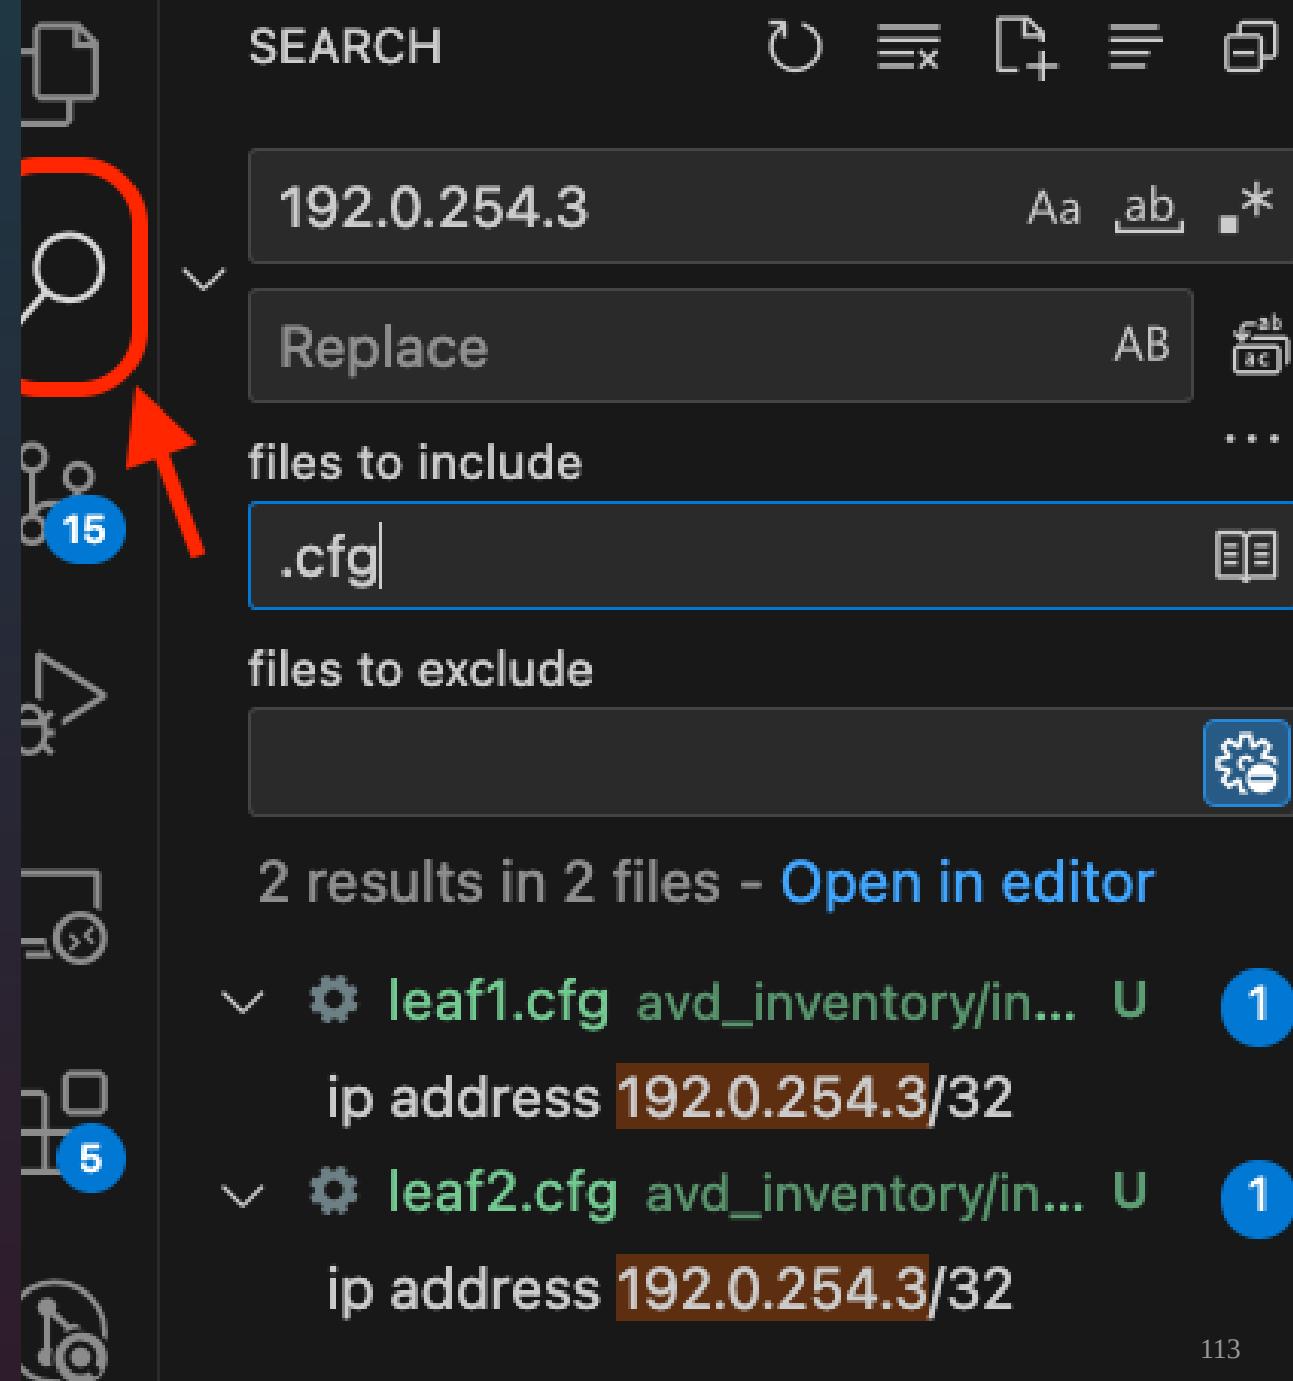

# Custom Structured Configuration

- As we discussed earlier, AVD is using different roles to produce EOS configuration from the input data.
- `eos_designs` is responsible of building low level data structures called `intended configs` from group and host vars.
- Intended configs are then used by  `eos_cli_config_gen` to parse Jinja2 templates and produce configs
- That also means that if  `eos_designs` overrides some key in group or host vars,  `eos_cli_config_gen` will not be able to use them directly.
- If there is a need to override some keys, `custom_structured_configuration_` prefix can be used.
- Please check the [AVD Documentation](#) for details.
- One weird example of using custom structured is configuring Ethernet breakouts starting with /4 with /1 configuration missing. Yes, that happens! 😊 In that case AVD will produce the configuration that will not result in a valid EOS config. We have to add some low level tweaks to make it work:

```
custom_structured_configuration_ethernet_interfaces:  
  - name: Ethernet12/1  
    speed: forced 25gfull
```

# Use Search When Working With AVD

- AVD provides a lot of data about your network.
- Use search functions to inspect this data when you are troubleshooting or simply looking for a specific variable value.
- An example on the right shows how you can quickly find the switches with a specific loopback IP and corresponding configuration in VSCode.
- This becomes more powerful at scale.

# Get a Lab

## Section 3.3

- A few words on lab options that you can use to test AVD

# Build A Lab for AVD Testing

Once upon a time in ancient Egypt a man was building a datacenter. But virtual labs did not exist back then. He failed and was cursed by gods ... ☠☠☠ <-- ancient server rack on the left

- You must have a lab!
- Have different instances of the lab that you can use for testing, learning, CI.
- Available options:
  - Physical - best, but costly and therefore hard to scale
  - Virtual - VMWare, KVM, EVE-NG, GNS, etc.
  - Containers - Containerlab, KNE, etc.

# Requirements for The Lab

- Must:
  - Automation / orchestration capabilities are critical
  - Functional
  - Multivendor
  - Free and open source
  - Can support your CI pipeline (if you go that far)
- Not critical:
  - GUI is overrated
- That is only an opinion. Your mileage may vary.
- Still no standard tool for the industry.

# Some Lab Options

- **Hardware**  
limited availability and normally used to test hardware based features only
- **VMWare**  
OK for basic testing, but not really a lab solution and limited automation capabilities in certain cases due to licensing restrictions
- **EVE-NG**  
Great way to start, big community. But you can do better. 😊
- **KVM**  
Multipurpose, easy to manage and automate. Reasonable VM footprint with KSM. Good choice.
- **Containerlab**  
Very polished and easy to use. Great orchestration tools. If cEOS is sufficient for testing - use it.
- **KNE**  
potentially useful for distributed large scale lab, but entry barrier is much higher comparing to cLab
- **Netsim**  
whatever it is, the list is already too long. 😊

# EVE-NG History

- Originally EVE-NG is KVM with custom kernel and GUI
- As EVE-NG is closed, not clear how big is the difference right now
- EVE-NG claims support for some interesting features, like UKSM
  - UKSM (Ultra Kernel Same-page Merging) development on original public Github is stale
  - Have not seen any contribution from EVE-NG back to the community
  - KSM works just fine

# KVM as a Virtual Lab

- Very robust solution, but with some complexity:
  - "Slow protocols" (STP, LACP, LLDP, etc.) require custom kernel or Open vSwitch
- No reasonable orchestration for virtual lab:
  - KVM is perfect for automation. But there is no solution available to automate virtual lab deployment without writing custom code/scripts
  - For that reason managing full scale virtual lab in KVM can be complex:
    - [Migrating from KVM to EVE-NG](#)
- KVM is perfect for a few VMs + cLab on the same host
- Examples of automated KVM deployment in the lab (or prod):
  - [CVP KVM Deployer](#)
  - ISO-based provisioning script (ask your SE)

# Containerlab

- Big appreciation to every cLab contributor for making the world a better place
- cLab is the best option to start with:
  - it's free, it's open-source, it is multi-vendor
  - very light footprint and very easy to use (even without advanced Docker skills)
  - portable (your lab is a Git repository)
  - perfect lab orchestration
- Reasons not to use cLab:
  - no container available for the OS of your choice
  - some required features are not available in the container ( cEOS: MPLS, multicast, etc.)
  - platform limitations (for ex., cEOS on ARM)
  - failover testing (do not try to emulate software upgrade or phy link failure using cLab!)
  - it's getting better every day!
- Containerlab has growing and active community. Start here:
  - [cLab quickstart](#)
  - [cLab workshop for Arista cEOS-lab](#)
